6789. *The Ayrshire breed* (*Ag* 880.), according to Atton (*Agriculture of Ayr* p. 421.) is the most improved breed of cattle to be found in the island not only for the dairy in which they have no parallel,

860

under similar soil, climate, and relative circumstances but also in feeding for the shambles. They are, in fact, a breed of cows that have, by crossing, coupling, feeding, and treatment, been improved and brought to a state of perfection, which fits them, above all others yet known, to answer almost in every diversity of situation, where grain and grasses can be raised to feed them, for the purposes of the dairy or for fattening them for beef. (*Atton*.)

6790. *The origin of the Ayrshire breed of cattle* is to be found in the indigenous cattle of the county of Ayr, improved in their size, shapes and qualities, chiefly by judicious selection, cross-coupling, feeding, and treatment, for a long series of time, and with much judgment and attention, by the industrious inhabitants of the county and principally by those of the district of Cunningham. (*Atton*.) The whole dairy breed in the county of Ayr is of mixed white and brown colours.

6791. *The size of the Ayrshire improved dairy cows* varies from 30 to 40 stones English, according to the quality and abundance of their food. If cattle are too small for the soil, they will soon rise to the size it can maintain and the reverse, if they are larger than it is calculated to support. (*Atton*.)

6792. *The shapes most approved of* are as follows:—"Head small, but rather long and narrow; the muzzle; the eye small, but smart and lively; the horns small, clear crooked, and their roots at considerable distance from each other; neck long and slender tapering towards the head, with no loose skin below; shoulders thin; fore-quarters light; hind-quarters large; back straight, broad behind the loins rather loose and open; carcass deep, and pelvis capacious and wide over the hips, with round fleshy buttocks; tail long and small; legs small and short, with firm joints; udder capacious, broad, and square, stretching forward, and neither fleshy low hung, nor loose; the milk veins large and prominent; teats short, all pointing outwards, and at considerable distance from each other; skin thin and loose; hair soft and woolly; the head, bones, horns, and all parts of least value, small; and the general figure compact and well proportioned." (*Atton*.)

6793. *The form of the Cunningham Ayrshire cow*, according to Robertson, is "very elegant, but must be seen to be well understood. So far as it may be explained in words, it is thus:—"The neck is small, the head little, the muzzle taper; the horns short, curved, and beeting upwards; the countenance mild; the body straight along the back from shoulder to tail; the limbs slender; the udder shaped like a well turned punch-bowl, and the paps widely set. The head, the neck, and the udder are the chief distinguishing points. The colour is generally brown, of many hues, from dark to yellow intermixed and mottled in many a varied form and proportion with white. Some few have a black ground, without any change in character; but almost none are of one colour only. In a whole herd of forty or fifty there will not two of them be alike in colour. In this respect exhibiting a diversity not unlike in a bud of tulips, and of as many hues and shades, in an endless variety of beauty. The bulls are generally good tempered and, like the cows, are also mild in the countenance. The usual produce of butter from these cows is ascertained to be about half their own weight (meaning the four quarters) in a year; but this requires that the pasture be good, and the cow otherwise well kept the whole season over. The produce of such a cow so kept will equal 94 lbs. Imperial weight per annum of butter and double that quantity of cheese. The medium produce in butter from Ayrshire milk is from five Imperial quarts. (*Robertson on Agriculture*, p. 505.)

6794. *The qualities of the Ayrshire dairy-cows* are of great importance. Firmness and docility of temper greatly enhance the value of a Ayrshire cow. One that is quiet and contented feeds at ease, does not break over fences, or hurt herself and other cattle; will always yield more milk, and is easier to manage than those that are of a turbulent disposition. To render them docile, they ought to be gently treated; frequently handled when young, and never struck or frightened. Some degree of hardiness, a sound constitution and a moderate degree of life and spirits, are qualities to be wished for in a dairy cow; and what those of Ayrshire generally possess. The most valuable quality which a dairy cow can possess is that she yields much milk. A cow in Ayrshire that does not milk well will soon come to the hammer. I have never seen cows any where that, under the same mode of feeding and treatment, would yield so much milk as the dairy breed of that district. Ten Scotch pints per day is no way uncommon. Several cows yield, for some time, twelve pints, and some thirteen or fourteen pints per day. Another quality of the

dairy breed of Ayrshire is, that, after they have yielded very large quantities of milk for several years, they are as valuable for beef as the Galloway cow, or any other breed of cows known in Scotland. They station as well, and their beef is not inferior to that of any other breed of cattle known in Britain." (*ibid.*)

6758. The cattle of the Highlands of Scotland are divided into a number of local varieties, some of which differ materially from others, probably owing to a difference in the climate and the quality of the herbage, rather than to their being sprung from races originally distinct, or to any great change caused either by selective or by crossing with other breeds. It is only of late that much attention has been paid to their improvement, in any part of this extensive country, and in the northern and central Highlands the cattle are yet, for the most part, in as rude a state, and under management as defective, as they were some centuries ago. These cattle have almost exclusive possession of all that division of Scotland including the Hebrides, marked off by a line from the Frith of Clyde on the west, to the Murray Frith on the north and bending towards the east till it approaches in some places very near to the German Ocean. Along the eastern coast, north of the Frith of Forth the Highland cattle are intermixed with various local breeds, of which they have probably been the basis. There are more or less marked distinctions among the cattle of the different Highland counties, and, in common language, we speak of the Inverness-shire, the Banffshire, &c. cattle, as if they were so many separate breeds, but it is only necessary in this place to notice the two more general variations, now clearly distinguishable by their form, size, and general properties.

6759. The most valuable of these are the cattle of the *Western Highlands and Isles*, commonly called the *Argyllshire breed* (fig. 861.) or the breed of the Isle of Skye, one of the islands attached to the county of Argyre. The cattle of the Hebrides are called *Kyloes*, a name which is often applied in the south to all the varieties of the Highland cattle, not as a late writer (*Dictionnaire Pratique d'Agriculture*, vol. ii. p. 158.) has imagined from the district in Ayrshire called *Kyle*, where very few of them are kept, but from their crossing, in their progress to the south the *Kyloes* or *ferries* in the mainland and Western Islands, where these cattle are found in the greatest perfection. (*General Report of Scotland*, vol. iii. p. 25.)

6760. The cattle of Orkney and Zetland are of a most diminutive size; an ox weighing about sixty pounds a quarter and a cow forty-five pounds. They are of all colours and their shapes are generally bad yet they give a quantity of excellent milk. Often rapidly when they are considered strong, hardy and excellent workers, when well trained to the yoke and so plentifully fed as to enable them to support labour.

6761. Of the *Fifehire cattle* Culley observes "You would at first imagine them a distinct breed, from their upright white horns, being exceedingly light-furred and thin-thighed, but I am pretty clear that it is only from their being more nearly allied to the *Kyloes*, and consequently less of the coarse kind of short horns in them. (*Culley* p. 63.) Notwithstanding this opinion, the cattle of the north-eastern counties of Scotland require, for every useful purpose, to be treated separately from the Highland breeds, and as all of them have a general resemblance, it will only be necessary in this place to notice the *Fife cattle* in particular. There are various traditions about the origin of this variety. It is said to have been much improved by English cows sent by Henry VII. to his daughter, the consort of James IV. who usually resided at the palace of Falkland, in that county, and as there is some resemblance between the cattle of Fife and Cambridgeshire, they are supposed to have been brought originally from the latter county. Others ascribe the origin of the present breed to bulls and cows sent by James VI. (James I. of England), in payment of the money which his obliging neighbours in Fife are said to have advanced for his equipment, when he went to take possession of the English throne. (*Report of Nassau and Murray* p. 315.)

6762. The prevailing colour of the *Fife cattle* is black, though sometimes spotted or streaked with white, and some of them are altogether grey. The horns are small, white, generally pretty erect, or at least turned up at the points, bending rather forward, and not wide spread like the Lancashire long-horned breed. The bone is small in proportion to the carcass, the limbs clean, but short, and the skin soft. They are wide between the hock-bones, the ribs narrow wide set and having a great curvature. They fatten quickly and fill up well at all the choice points, are hardy feet, and travel well, and are excellent for labour both at plough and cart. A good cow of this breed gives from eighteen to twenty four quarts of milk per day yielding from seven to nine pounds of butter and from ten to twelve pounds of cheese per week (twenty four ounces to the pound) for some months after calving. (*ibid.* Report, p. 251 and 253.)

6763. The cattle of *Aberdeenshire* the largest of which are said to have been produced by crossing with Fife bulls, have been long highly esteemed in the southern markets. It is observed, that every succeeding generation of them has increased in size for the last thirty years, and that the native breed has doubled its former weight since the introduction of turnips. (*Aberdeenshire Report*, p. 463.) The colour is commonly black, but there are many of a red and brayed colour. They are thinner in the buttock, in proportion to their weight, and deeper in the belly in proportion to their circumference, than the west Highlanders, and they yield a much larger quantity of milk. Many of them are brought to the south of Scotland and kept during winter in the straw yards for which they suit better than smaller cattle, as they are not so impatient of confinement. The ordinary weight of middle-aged oxen at from three to five years old, is from forty to fifty stone, but after they have worked for some time and thoroughly fattened, they have been known to reach double this weight.

861. Of the *Welsh cattle* (fig. 862.) there seem to be two distinct kinds. The large sort are of a brown colour with some white on the rump and shoulders, denoting a cross from the long-horns, though in shape not the least resembling them. They are long in the legs, stand high according to their weight, are thin in the thigh and rather narrow in the chine, their horns are white and turned upwards, they are light in flesh, and next to the Devon, well formed for the yoke, have very good hoofs, and walk light and firmly. The other sort are much more valuable; colour black with very little white; of a good useful form, short in the leg, with round deep bodies; the hide is rather thin with short hair; they have a likely look, and a good eye; and the bones, though not very small, are neither large nor clumsy; and the cows are considered good milchers." (*Parishman on Low Black*, vol. i. p. 135.)

862. The *Alderney cattle* are to be met with only about the sands of a few good landholders, where they are kept chiefly for the sake of their milk, which is very rich, though small in quantity. This race is considered, by every competent judge, as too delicate and tender to be propagated to any extent in Britain, at least in its northern parts. Their colour is mostly yellow or light red, with white or mottled faces. They have short crumpled horns, are small in size, and very ill-shaped; yet they are two-bred in

general; and their beef, though high coloured, is very well flavoured. I have seen, says Culley some very useful cattle bred from a cross between an Alderney cow and a short-horned bull.

6004. The Irish cattle, Culley thinks, are a mixture breed between the long horns and the Welsh or Scotch, but more inclined to the long-horns, though of less weight than those in England.

6004. The last variety of cattle we shall mention is one entirely of luxury. It is the wild breed (Ag 865.) which is found only in the parks of a few great proprietors, who preserve the animals as curious and

863

ornamental, or for the sake of their high-flavoured beef. Those kept at Chillingham Castle, in Northumberland a seat belonging to the Earl of Tankerville have been very accurately described in the *Northumberland Report* and in Culley's book on live stock, so often quoted. Their colour is invariably of a creamy white, mottled black the whole of the inside of the ear and about one third of the outside, from the tips downward, red horns white with black tips very fine, and bent upwards some of the bulls have a thin upright mane, about an inch and a half or two inches long. The weight of the oxen is from thirty five to forty five stone and the cows from twenty five to thirty five stone the four quarters (Southern pounds to the stone). The beef is finely marbled, and of excellent flavour. From the nature of their pasture and the frequent agitation they are put into by the curiosity of strangers, it is scarcely to be expected they should get very fat; yet the six years old oxen are generally very good beef from which it may be fairly supposed that in proper situations they would feed well.

6005. The habits of these animals are entirely rude. At the first appearance of any person they set off in full gallop and at the distance of about two hundred yards, make a wheel round and come boldly up again tossing their heads in a menacing manner. On a sudden they make a full stop, at the distance of forty or fifty yards looking wildly at the object of their surprise, but, upon the least motion being made they all again turn round, and fly off with equal speed, but not to the same distance, forming a shorter circle and again returning with a bolder and more threatening aspect than before they approach much nearer probably within thirty yards, when they again make another stand and again fly off. This they do several times, shortening their distance and advancing nearer and nearer till they come within such a short distance, that most people think it prudent to leave them, not choosing to provoke them farther.

6006. When the cows calve they hide their calves for a week or ten days in some sequestered situation and go and suckle them two or three times a day. If any person comes near them, the calves clap their heads close to the ground, and lie like hares in form, to hide themselves. This is a proof of their native wildness, and is corroborated by the following circumstance that happened to the writer of this narrative (Bailey of Chillingham), who found a hidden calf two days old, very lean and very weak. — On stroking its head it got up, pawed two or three times like an old bull, bellowed very loud, stepped back a few steps, and bolted at his legs with all its force. It then began to paw again bellowed stepped back and bolted as before, but knowing its intention and stepping aside, it missed him, fell and was so very weak that it could not rise, though it made several efforts but it had done enough the whole herd were alarmed, and, coming to its rescue obliged him to retire for the dams will allow no person to touch their calves without attacking him with impetuous ferocity.

6007. When a calf is to be sacrificed, the park-keeper marks the place where it is hid, and when the herd are at a distance, takes an assistant with him on horseback, they tie a handkerchief round the calf's mouth to prevent its bellowing, and then perform the operation in the usual way, with as much expedition as possible. When any one happens to be wounded, or is grown weak and feeble through age or sickness, the rest of the herd set upon it and gore it to death. (Culley p. 75.)

6008. The mode of killing them was, perhaps, the only remains of the grandeur of ancient hunting. On notice being given that a wild bull would be killed on a certain day the inhabitants of the neighbourhood came mounted and armed with guns, &c. sometimes to the amount of a hundred horse and four or five hundred foot, who stood upon walls or got into trees, while the horsemen rode off the bull from the rest of the herd until he stood at bay when a marksman dismounted and shot. At some of these huntings twenty or thirty shots have been fired before he was subdued. On such occasions, the bleeding victim grew desperately furious from the smarting of his wounds, and the shouts of savage joy that were echoing from every side, but from the number of accidents that happened, the dangerous mode has been little practised of late years, the park-keeper alone generally shooting them with a rifled gun at one shot.

#### SUMMARY 2. Criteria of Cattle for various objects and purposes.

\*6009. The criteria of a well-made bull, to whatever breed he may belong, are, according to Culley as follows: — The head should be rather long and the muzzle fine; his eyes lively and prominent, his ears long and thin his horns wide, his neck rising with a gentle curve from the shoulders, and small and fine where it joins the head the shoulders moderately broad at the top, joining full to his chine or croupe and chest backwards, and to the neck-vein forwards; his bosom open, breast broad, and projecting well before his hips his arms or fore-thighs muscular and tapering to his knee; his legs straight, clean, and very well-boned; his oblique and chest so full as to leave no hollow behind the shoulders the plates strong, to keep his belly from sinking below the level of his breast; his back or loin broad, straight, and full his ribs rising one above another in such a manner that the last rib shall be rather the highest, leaving only a

small space to the hips or loins, the whole forming a round or barrel-like carcass; his hips should be well placed, round, or globular, and a little higher than the back. The quarters from the hip to the rump long, and instead of being square, as recommended by some, they should taper gradually from the hips backward, and the tibia or past-bones not in the least protuberant; rump close to the tail, the tail broad, well haired, and set on so high as to be in the same horizontal line with his back. Bulls should be consistently well fed, and kept in proper condition, never being confined to ride before they are three years old, so when the contrary is the practice they never attain to perfect growth. It is observed by Lawrence, that the above description delineates that barrel-shape which Bakewell supposed most advantageous for all kinds of animals intended to be fed for slaughter, or even used for labour.

6510. The criteria of excellence in most cattle in general are thus given by John Wilkinson of Linton near Nottingham, an eminent breeder (*Remarks on Cattle, &c. 1861*). "The head ought to be rather long, and muscular; fine the circumference of the neck and place which indicates a disposition to get fat, the horns fine, the neck light, particularly where it joins the head, the breast wide and projecting well before the legs. The shoulder moderately broad at the top, and the joints well in, and when the animal is in good condition, the chine so full as to leave no hollow behind it. The fore flank well filled up, and the girth behind the shoulder deep, the back straight, wide, and flat. The ribs broad, and the space between them and the hips small. The flank full and heavy, the belly well kept in and not sinking low in the middle, but so formed that a cross section of it would resemble an oval, whose two ends are of the same width, and whose form approaches to that of a circle, or of an ellipse whose eccentricity is not great (the whole forming, not a round or barrel-like carcass as some have expressed it, for this would leave a deficiency both in the upper and lower part of the ribs) the hips globular wide as roses, and on a level with the back steers, the hind quarters, that is, from the hips to the extremity of the rump, long and straight the rump points flat, and coming well up to the tail, the twist wide, and the seam in the middle of it so well filled that the whole may very nearly form a plane perpendicular to the line of the back. The lower part of the thigh small. The tail broad and fat towards the top, but the lower part thin. The legs straight, clean, and fine-boned. And when the animal is in high condition, the skin of a rich and silky appearance. These appear to be the most material points for the formation of true symmetry in cattle: there are others of a minor consideration, which will readily be suggested by attention and experience.

6511. The criteria of an *or well adapted to labour* differ from the above only in requiring long and strong legs, and broad hairy feet and hoofs.

6512. The criteria of a *beautiful cow* according to Wilkinson, may be thus expressed —

She's long in her face, she's fine in her horn,  
She'll quickly get fat, without cake or corn,  
She's clear in her jaw, and full in her chine,  
She's heavy in flank, and wide in her loin.

She's broad in her ribs, and long in her rump,  
A straight and flat back, with never a hump  
She's wide in her legs, and calm in her eye,  
She's fine in her shoulders, and thin in her thigh.

She's light in her neck, and small in her tail,  
She's wide in her breast, and good at the pail,  
She's fine in her bone, and silky of skin,  
She's a grazer's without, and a butcher's within.

6513. *Cattle's marks of a good cow* are these — Wide horns, a thin head and neck, dewlap large, fine hair, broad back, large deep belly, the udder capacious, but not too fleshy, the milk-veins prominent, and the legs tending for labour. Legs long and large, buttocks broad and fleshy, tail long and pliable, legs proportionable to the size of the carcass, and the girth short. To these outward marks may be added a gentle disposition, a temper free from any vicious tricks, and perfectly manageable on every occasion. On the other hand, a cow with a thick head and a short neck, prominent back bone, slender chest, belly tucked up, small udder or fleshy bag, short teats, and thus buttocks, is to be avoided as totally unfit for the purposes either of the dairy maid, the suckler or the grazer. The most valuable cows are those which are bred in Yorkshire, Staffordshire, and upon the strong lands in other part of England, and in Ayrshire in Scotland.

6514. The criteria of excellence in cattle, as derived from colour are of no importance, and all that can be said is, that white and red cattle are less hardy than the black-haired.

6515. The criteria of age in cattle are derived from the teeth and horns. At the end of about two years they shed their first four teeth which are replaced by others, larger but not so white, and before five years all the incisors are renewed. These teeth are at first equal, long, and pretty white; but, as the animals advance in years, they wear down, become unequal, and grow black. These animals, according to some, likewise shed their horns at the end of three years, and they are replaced by other horns, which, like the second teeth, continue thus, however is totally or partially denied by practical men, and our statement of it as a fact without qualification has been objected to in the *American Farmer*. The manner of the growth of these horns is not uniform, nor the shooting of them equal. The first year, that is, the fourth year of the animal's age, two small-pointed horns make their appearance, nearly straight, smooth, and towards the head terminated by a kind of button. The following year this button moves from the head, being impelled by a horny cylinder which lengthening in the same manner, is also terminated by another button, and so on for the horns continue growing as long as the animal lives. These buttons become annular joints or rings, which are easily distinguished in the horn and by which the age of the creature may be easily known, counting three years for the point of the horn, and one for each of the joints or rings. The cow continues useful for more than twenty years, but the bull loses his vigour much sooner. It is common with dealers to obliterate these rings, by shaving the horns, in order to conceal the age of the beast.

6516. The terms applied to different ages are as follows — A young castrated male, after the first year, is called a *stallion*; when a year older, a *stall*, or *stallion*; at five years old, an *ox*. A female, after the first year is called a *heifer*, or *cow*; when about to bring a calf, she is called a *young cow*. A castrated female is called a *spayed heifer*. Certain of the Welsh and Border cattle of rather a coarse and sturdy kind, are denominated *rutts*. Bullback is the general term for any full-grown male cattle, fat or lean.

6517. The natural duration of life with the bull and cow may be stated at upwards of twenty years, to nearly the end of which the latter is useful with her milk, but the former generally loses his vigour consequently his use, many years earlier.

§

### Summary 3. Breeding of Horned Cattle

6518. The objects to be kept in view in breeding cattle are, forms well adapted for fattening, for producing milk, or for labour. These objects have each of them engaged the attention of British agriculturists, but experience has not hitherto justified the expectation that has been entertained of combining all these desirable properties, in an eminent degree, in the same race. That form which indicates the property of yielding the most milk, differs materially from that which we know from experience to be combined with early maturity and the most valuable carcass, and the trends which are understood to give the greatest

weight of meat for the food they consume, and to contain the least proportion of oil, are not those which possess, in the highest degree, the strength and activity required in the beasts of labour.

6818. *A disposition to fatten, and a tendency to yield a large quantity of milk cannot be united.* The form of the animal most remarkable for the first, is very different from that of the other; in places of being flat in the sides, and high in the body as all good milkers are, it is high-sided and light-bellied. In a word the body of the animal well adapted to fatten is barrel-shaped, while that of the milker is widest downwards. It is not probable therefore, that the properties of two breeds of cattle, so opposite in form and general appearance, can ever be united in the same animal.

6819. *The long and short horned breeds have hitherto been in possession of the best part of the island;* but various others, as the Ayrshire, the Galloway cattle, and Kyles, might be bred with advantage in many situations, so as to be more profitable than either the short-horns or the long horns. These breeds of cattle as true quick-feeders, and being kindly-fleshed, or excellent eating beef have established their character in the first market in the island. The Scotch or Kyles are better adapted to cold exposed heathy, mountainous situations, than any other breed we have. Particular breeds are probably best adapted to particular situations; on which ground, breeders of cattle should endeavour to find out what breed is the most profitable and best suited to their situations, and to improve that breed to the utmost, rather than to try to unite the particular qualities of two or more distinct breeds by crossing. The latter is a precarious practice, for we generally find the produce inherit the coarseness of both breeds, and rarely attain the good properties which the pure distinct breeds individually possess. In order to have good cattle of any breed, particular regard must be paid in selecting those that are the most complete and perfect in their form, shape, and other qualities, and to breed from them.

6821. *An extraordinary degree of attention has been paid to the breeding of cattle in England since the time of Bakewell, and some illustrious names might be mentioned in addition to those of professional farmers.* Pedigrees of the best cattle have been preserved with no less care, in several places than those of race horses; and, in the selection of breeders, the properties of the family from which they have descended are matters of scarcely less importance than the form of the young animals themselves. The extraordinary prices paid for the best-bred bulls and cows show that this attention has not been without its reward.

6822. *The best bulls are either let out for the season, or cows are brought to them at a certain rate per head.* The practice of letting bulls is said to have originated with Bakewell (*Marshall's Midland Counties* vol. i. p. 536.) who, early in his career, let a bull for one hundred and fifty two guineas to be used only four months (*Parkinson*, vol. ii. p. 469.) and five guineas per cow were about that time commonly paid to him and other eminent breeders.

6823. *The age at which bulls should begin to be employed, and the number of seasons they should be allowed to serve, as well as the age at which the females should begin to breed, are points regarding which practice is by no means uniform.* In the midland counties, the bulls are pretty commonly allowed to leap while yearlings; and if good stock-keepers are kept on as long as they will do business, perhaps till they are ten or twelve years old. In other places they are employed only three seasons, for the first time at two years old. The females in many instances, bring their first calf at the age of two years, but more commonly perhaps not till they are a year older; and in some of the Highland districts, where owing to a want of proper nourishment in their infancy they are later in coming to their full growth, the females do not often become mothers till they are about four years old.

6824. *The period of gestation with cows has been found, upon an average of a great number of experiments, to be about forty weeks.* M. Tessier communicated to the National Institute of France the following observations on this subject. — Of 180 cows, 14 calved from the 24th to the 26th day, 5 on the 27th 50 on the 28th 68 on the 29th to the 30th 50 on the 30th, and 5 on the 31st. Cows seldom bring more than one calf at a time. When they produce twins, one of them a male and the other a female, the latter which is called a free martin, is commonly considered to be incapable of procreation, yet there seem to have been well authenticated instances to the contrary (*Farmer's Magazine*, vol. vii. p. 468. and vol. viii. p. 466.)

6825. *The most desirable period for putting cows to the bull is midsummer* in order that they may be dropped in spring, and have the whole of the grass season before them. Where no regular system is followed, and cows are sent to the bull merely because they are in heat, calves will be dropped at all seasons but, except in those districts where the feeding of calves is an object of importance, spring is probably the most advantageous time; as the calves, having all the grass season before them, become sufficiently strong for enduring the change to a less agreeable food in the ensuing winter. A calf newly weaned seldom thrives well during that period, unless it is pampered with better food than usually falls to the share of young animals. By midsummer the cows are readier to take the bull than at any other season, and will bring calves in proper time. If a cow goes till after May before she calves, the calf will be too weak in the winter following; and the dam will not be so ready to take the bull again, but will often grow barren.

6826. *It is not always the best milch cow that has the best calf* even though the external circumstances should be similar; and vice versa, a sorry cow may have a good calf. These remarks apply to this breed as well as to others. The immediate progeny of a good milker may be an indifferent milch cow; but in the second remove, the good milking quality of the grandam returns. This has often been observed, and without any of the causes being imputable to the sire. (*Robertson*, p. 571.)

#### SUBJECT. 4. Rearing of Horned Cattle

6827. *The mode of rearing calves is various.* There can be little doubt but that the best and most natural mode is that of allowing them to suck their dams, at least for some length of time after they are brought forth.

6828. *In Yorkshire and most parts of Scotland, the usual method is to give them milk to drink, there being few instances where they are allowed to suck.* For the first two or three weeks, they mostly get milk warm from the cow; but for the next two or three weeks, half the new milk is withdrawn and skim-milk substituted in its stead; and at the end of that period, the new milk is wholly withdrawn: they are then fed on skim-milk alone, or sometimes mixed with water till they are able to support themselves by eating grass, or other food of that sort.

6829. *In Cheshire, the practice is to allow the calves to suck for the first three weeks.* They are then fed on warm new whey or scalded whey and buttermilk mixed; with the green whey water is frequently mixed and either oatmeal or wheat and bean flour added. A quart of meal or flour is thought sufficient to mix with forty or fifty quarts of liquid. Oatmeal gruel and buttermilk, with an addition of skimmed milk, are also used for the same purpose. Some one of these prepared kinds of food is given, night and morning for a few weeks after the calves are put on that diet, but afterwards only once a day till they are three months old or more.

6830. *In Gloucestershire the calves are not allowed to suck above two or three days* they are then fed on skim-milk, which is previously heated over the fire. When they arrive at such an age as to be able to eat a little, they are allowed split beans, or oats and cut hay and water is mixed with the milk.

6831. *In Sussex it is common to allow the calves to suck for ten or twelve weeks, or to wean them at the end of three or four; and give them a liberal allowance of skim-milk for six or eight weeks longer.*

6832. *In Middlesex it is usual, in rearing calves, to give them a pailful, containing about a gallon, of milk warm from the cow morning and evening, for eight or ten weeks; or, which is certainly the most*

agreeable to nature, and therefore to be preferred to any other that can be adopted, to allow the calf to suck its dam, as it is sometimes done in the county of Sussex, and generally in Wiltshire.

8523. *According to Marshall*, the best method is this — The calves suck a week or a fortnight, according to their strength (a good rule) new milk in the pail, a few meals next, new milk and skim-milk mixed, a few waste meals; then, skim-milk alone, or porridge made with milk, water ground oats, &c. and some times clover, until chosen-making commences after which, whey porridge, or sweet whey in the feed; being careful to house them in the night, until warm weather be confirmed. (*Midland Counties*, vol. 1 p. 328.) This method of suckling is not, however free from objection; and, in the ordinary practice of rearing calves, it is held to be a preferable plan to begin at once to teach them to drink from a pail. The calf that is fed from the teat must depend upon the milk of its dam, however scanty or irregular it may be; whereas, when fed from a dish the quantity can be regulated according to its age; and various substitutes may be resorted to, by which a great part of the milk is saved for other purposes, or a greater number of calves reared upon the same quantity. (*General Report of Scotland*, vol. lii. p. 51.) Yet it would seem to be a good practice to allow calves to suck for a few days at first, if there were no inconvenience to be apprehended, both to themselves and their dams, from the separation afterwards.

8524. *When fed from the pail*, the average allowance to a calf is about two English wine gallons of milk daily for twelve or thirteen weeks at first, fresh milk as it is drawn from the cow, and afterwards skim-milk. But where it is three or four weeks old a great variety of substitutes for milk are used in different places, of which linseed-oil cake, meal, and turnips, are the most common.

8525. *Where calves are reared with skim-milk* it should be boiled, and suffered to stand until it cools to the temperature of that first given by the cow or a trifling degree more warm and in that state it should be given to the calf. Milk is frequently given to calves warm only but that method will not succeed so well as boiling it. If the milk be given warm only, it will cause the calf to sick or purge. When this is the case, put two or three spoonfuls of rumour in the milk, and it will soon stop the looseness. If on the contrary the calf is found, bacon broth is a very good and safe thing to put into the milk. One gallon of milk per day will keep a calf well at first. The usual allowance is about double after the first eight or ten days, and this is increased with the age of the animal. After it is thirteen weeks old, it will do very well upon grass or other food, without any milk at all. A calf may then be supported without milk, by giving it hay and a little wheaten bran, once a day with about a pint of oats. The oats will be found of great service as soon as the calf is capable of eating them. The bran and oats should be given about mid-day; the milk in portions, at eight o'clock in the morning, and four in the afternoon. But whatever hours are chosen to be set apart for feeding the calf, it is best to adhere to the particular times, as regularity is of more consequence than many people think. If the calf go but an hour or two beyond his usual time of feeding, he will find himself uneasy and pine for food. It is always to be understood, that calves reared in this manner are to be enticed to eat hay as early as possible and the best way of doing this is to give them the sweetest hay that can be got, and but little at a time. Turnips or potatoes are very good food, as soon as they can be eaten by them and they are best cut small and mixed with hay oats, bran, and such articles. It may be observed, that it is not absolutely necessary to give milk to calves after they are one month old, to wean them gradually two quarts of milk, with the addition of linseed oil led in water to make a gruel, given together, will answer; and by diminishing the milk gradually the calf will soon do without it. Hay tea will do with the like addition of two quarts of milk, but it is not so nutritious as linseed. It is a good method of making this, to put such a proportion of hay as will be necessary into a tub, then to pour on a sufficient quantity of boiling water cover up the vessel, and letting the water remain long enough to extract the virtues of the hay. When bacon or pork is boiled it is a good way to preserve the liquor or broth and mix it with milk for the calves.

8526. *In summer calves may sometimes be reared on hay only*; but when reared in a wetter they must be fed with hay and clover-hay is probably the best of any for this use. Calves may also be reared with porridge of different kinds, without any mixture of milk. It is sometimes a good and convenient plan the author of the *New Farmer's Calendar* says to bring up calves under a step-mother an old cow, with a tolerable stock of milk, will suckle two calves, or more, either turned off with her, or at home, keeping them in good condition until they are old enough to shift. They ought to suck the first of the mother's milk for two or three days, although many are weaned without ever being suffered to suck at all. Calves whether rearing or fattening should also always suck before milking the cow being milked afterwards, as the first and thinnest of the milk is sufficiently rich. Old milk will, perhaps, nourish a very young calf but the effect will go off without any ill consequences. He observes, that the Duke of Northumberland's recipe is to take one gallon of skimmed milk, and to about a pint of it add half an ounce of common treacle, stirring it until it is well mixed then to take one ounce of linseed-oil cake finely pulverised, and with the hand let it fall gradually in very small quantities, into the milk stirring it in the mean time with a spoon or ladle, until it be thoroughly incorporated then let the mixture be put into the other part of the milk, and the whole be made nearly as warm as new milk when it is first taken from the cow and in that state it is fit for use. The quantity of oil-cake powder may from time to time be increased as occasion may require, and as the calf becomes used to the flavour of it. Crook's method is to make a jelly of one quart of linseed, boiled ten minutes in six quarts of water which jelly is afterwards mixed with a small quantity of the best hay tea. On this he rears many calves without milk. He thinks many calves are annually lost by artificial rearing, and more brought up with poor and weak constitutions.

8527. *When calves are dropped during the grass season*, Donaldson observes, they should be put into some small home-close of sweet rich pasture after they are eight or ten days old not only for the sake of exercise, but also that they may the sooner take to the eating of grass. When they happen to be dropped during winter or before the return of the grass season, a little short soft hay or straw or sliced turnips should be laid in the trough or stall before them.

8528. *Castration is performed both on male and female calves*, when neither are intended for procreation. On cow calves, however, it is generally omitted but in Norfolk no distinction is made as to sex males and females are equally objects of rearing, and are both equally subject to castration, it being a prevailing custom to pay all heifers intended to be fatted at three years old but such as are intended to be finished at two years old are it is believed, pretty generally left "open" as are, of course, those intended for the dairy. There are two reasons for this practice they are prevented from taking the bull too early, and thereby frustrating the main intention and by this precaution may be more quietly, and are kept from voting at the time of fating. This may be one reason why spayed heifers are thought to fatten more kindly at three years old, and to be better finished, than open heifers.

8529. *The time for performing the operation of castration in horned cattle* so in all kinds of live stock, is while the animals are yet very young, and just so strong as to endure this severe operation without any great danger of its proving fatal. The males, accordingly, are cut commonly when about a month old, and the females at the age of from one to three months but in Galloway where more heifers are spared than perhaps in all the island besides, this is seldom done till they are about a year old.

8530. *The best time for rearing calves* is the spring; but that operation must depend in some degree on the time when the calf was dropped. Such as are weaned during autumn or winter however, seldom do any good. At the season when the calf is weaned from the teat, it ought to be turned abroad in the day-time, into a small close or orchard near the yard where there is a good bite of grass, which may be expected at the time of the year when the weaning-calves are of this age and, as there will generally be more than one calf weaned in a season, they will each be company for the other and become in a short time accustomed to their situation. It is to be observed, that this pasture should be at some distance from that where the dams are turned, and that there be neither ponds nor ditches, nor any annoyances which might endanger the lives of these youthful animals and, in order to habituate them still more

to their pasture, milk-pottage should be carried to them at each of their feeding hours. For the first month or six weeks, therefore, ought every night to be brought out of the meadow and lodged in the pens; but after this time they may be left in the pasture as well in the night seasons as in the day, and at this time their food may be lowered by degrees till it be at length reduced to simple water only. For when the calves get to the age of twelve or fourteen weeks, they will no longer require the aid of this sustenance, but will be able to satisfy their appetites with grass. Care, however, must be taken throughout the summer that they be frequently shifted from one pasture to another, in order that they may be kept up in good flesh, and enabled to grow away with the utmost celerity. At Michaelmas, or soon after the calves should be taken into the yard, and if they were allowed the indulgence of a small close to themselves it would be still better.

6841 *The treatment of young cattle* from the time they are separated from their dams or are able to subsist on the common food of the other stock, must entirely depend upon the circumstances of the farm on which they are reared. In summer their pasture is often coarse, but abundant, and in winter all good breeders give them an allowance of succulent food along with their dry fodder. The first winter they have hay and turnips; the following summer coarse pasture; the second winter straw in the field yard, and a few turnips once a day in an adjoining field just sufficient to prevent the straw from larding them too much the next summer tolerably good pasture; and the third winter as many turnips as they can eat and are in every respect treated as fattening cattle. (Dunlop, p. 67.)

6842 *The method of managing young cattle during the first winter is*, according to Donaldson pretty generally the same in every part of the island. They are generally housed, sometimes bound up to the stall, but more frequently allowed to remain at freedom. The way of feeding them in England is chiefly with hay or hay and straw mixed, and in Scotland sometimes with hay but more frequently bray and turnips. They are mostly turned out on some of the inferior pastures on the farm in the following summer and maintained the second winter on straw in the straw yard, or in boules or sheds erected for the purpose. Some farmers in the more northern parts of the kingdom, from being situated at a distance from any market at which they can dispose of stalled beef very frequently give a considerable part of their turnip crop to their young cattle. This is, he thinks, an excellent practice, and one that ought to be followed, even by those who, from being better situated with regard to markets, can adopt other methods of using turnips to advantage. The benefit of green winter food for live stock is so great, that there is probably, he says, no way in which turnips can be used by which the farm or the farmer would reap greater benefit, than by giving the young cattle a daily allowance during the first two or three winters.

#### SUBJECT 5 Fattening Calves by Suckling

6843 *The most advantageous stock for suckling calves* for the butcher is that sort of cow which gives the greatest quantity of milk, richness of quality being not so great an object, or as well adapted to the intended purpose. The Friesian cows are to be preferred in this view, not, however, to white calves of the same, but of a smaller breed, perhaps Devon calves surpass all others as sucklers whether for quickness of proof, or beauty of the veal they are not, however to be procured but in or near their own country.

6844 *The method most commonly employed in fattening calves is*, to allow them to suck, as by this method the object is probably not only sooner, but more effectually attained than by any other means. The period which is necessary for fattening calves in this way must be different, according to circum-  
stances, but it is generally from seven to nine weeks, however, in the dairy districts where milk is considered a valuable article scarcely half that time is allowed. There is another method, which is, to give them the milk to drink, and when that is done, it is given them morning and evening a run from the cow and the quantity increased according to their age and strength. In whatever way they may be managed they should be kept in pens in a close house, and well littered. The author of the *Synopsis of Husbandry* observes that as it is necessary that the calves should lie always quiet in order that they may indulge in sleep at those times when they are not employed in sucking, it seems proper that the cow house should be situated in the most retired part of the yard, and that the pens should be kept as dark as possible. But notwithstanding this caution, the calves should in no means be suffered to lie too hot in the summer time, which would be apt to produce a sickness amongst them. I admit, therefore, an occasional draught of fresh air, let a window be cut in each pen, with shutters adapted to the same, and let these windows be opened whenever the closeness of the atmosphere indicates it to be necessary. In the summer season, they should rarely, if ever, be closely shut, and when it is required the stream of air may be increased by opening the cow house door at the opposite end of the building. Each calf should have a collar round his neck, with which the attendant may direct him in his sucking, but should never be fastened up in the pen. It is necessary that the pens be kept constantly well littered with the cleanest wheat straw a proportion of which should be thrown in to them every day cleanliness being a most essential article in the fattening of every animal, and not more necessary to any than to the calf, which but for this precaution, would in a short time demonstrate the ill effects of lying on his accumulated dung, which of all animals is the most offensive and of a quality highly septic. As the calves are yearned they are to be taken into the pens, and suckled by their own dams, which at first will yield a far greater quantity of milk than is necessary for their offspring, so that another calf may be suckled thereon, or the cow may be milked and the cream be reserved for butter or applied to any other use that the owner may think proper. As the calf increases in size, it will require a larger quantity of milk, but whilst calves are young one good cow will yield a noble supply for two, and when the whole produce is deemed good for one calf another new milk cow should be provided, and these two cows will abundantly supply the three calves with milk till the oldest is fit for the butcher, after which if necessary a fresh suckler may be brought in and the business be carried on progressively by keeping the house constantly supplied with calves, so that the whole milk may be sucked, as the dairy and the fattening of calves by sucking cannot be conveniently united.

6845 *The only advantage which suckling cows have, over giving calves milk to drink, is*, that the action of sucking induces a greater secretion of saliva, which, by promoting digestion accelerates the growth and fattening of the young animal, cannot be doubted, but the secretion of that fluid may be likewise promoted, by placing an artificial teat in the mouth of the calf and giving it the milk daily and at the natural temperature. In the dairy districts of Scotland the dairy maid puts one of her fingers into the mouth of the calf when it is fed, which serves the purpose of a teat, and will have nearly the same effect as a natural teat, in inducing the secretion of saliva. If, then, or an artificial teat of leather be used, and the milk given slowly before it is cold, the secretion of saliva may be promoted to all the extent that can be necessary, besides that secretion is not confined to the mere period of eating, but, as in the human body, the saliva is formed, and part of it is swallowed at all times. (Aston's Dairy Book p. 67.)

6846 *Young calves when permitted to suck their dams*, are often assailed with a lax or scouring, to prevent which the calves for the first fortnight or three weeks may be stinted in their allowance, and at the same time due care should be taken that they do not prove decrease in flesh for want of milk. But after this age they should be allowed to suck as long as they choose, and every means ought to be made use of to increase their appetite, and render them more eager after their food. Chalk may be given for this purpose, as well as for giving to the flesh a deeper whiteness. An excellent antiscorbutic remedy has been already given. (253.) Salt sprinkled in the trough will likewise act as a stimulant to the appetite, besides which, it is a common practice with some people to cram their calves with balls compounded of steep pounded shell, and milk, with the addition of a small quantity of common gum. Of these balls they give

two, about the size of a wheaten, once a day, or oftener, to each calf. These balls, being very nutritious, in some degree supply the place of milk, and at the same time the experienced milkmen observe on the creature as it suckles, and thus, by compelling them to sleep, increase their disposition to fatten; but where milk can be had in sufficient abundance, it is never worth while to have recourse to these artificial aids. When the demands of the calf, however, are beyond the ability of the poor these balls come seasonably to their relief. In order that the calves may be provided with sufficient store of milk, the pastures should be changed, whenever the cows are found to be deficient in this particular; and in the winter time, such food as is of a succulent nature as grubs, turnips, &c., should be always at hand to supply the want of grass; and these, with a due allowance of the sweetest hay should be their constant aliment during the time that the cows are confined to the yard.

604. *The prices of sucking calves vary according to the goodness of the young animal, and the time of year when the purchase is made.* In general, sucklers fetch the largest price in summer, when veal sells the cheapest, and the reason of this arises from the smaller number to be met with at that time than in the spring. When calves are slaughtered at six weeks or two months old, the veal is seldom of a good colour, neither has the flesh of these young calves a taste equal to that of animals suffered to live a few weeks longer. To obtain colour and flavour it is necessary that the calves should be maintained with plenty of milk, and managed as before directed, till they arrive at the age of eight or ten weeks, according to the season of the year the more or less kindly state of the calf the particular demand of the market, or other accidental circumstances. In the summer season, it may be proper to dispose of them at an earlier period than in the winter; not only on account of their growing away with greater celerity in warm weather but likewise because of the increased demand for small veal, which is then most saleable. During the last three or four weeks, blood should frequently be drawn from the calf, which will be a likely means towards rendering the veal of a colour delicately white; a circumstance so much attended to by the butcher that he will commonly depreciate such calves as, from the appearance of their eyes, are likely to die black, as they term it, though in other respects not to be despised.

604. *Calves are generally suckled a shorter time than those afterwards brought in to supply their place.* The first obvious reason for this difference in their favour is, their having been permitted to remain in the place where they were first dropped, and having always continued to suck the milk of their dam, which must in all reason be supposed of a more nutritious quality to them than that of any other cow. Secondly, the cow having so lately calved the aliment nourishes and fattens in a higher degree than when the animal becomes stale-milked. Cow calves are observed to fatten more luxuriantly than the male or bull-calves and the latter are much coarser framed than the former and their flesh less delicate in taste. Calves of the largest size are fattened in Essex, where the business of suckling seems to be better understood, and more properly conducted than in any other county and where the farmer keeps the calves to a greater age than in any other part of the kingdom.

6049. *Murdoch* is clearly of opinion, that to suckle calves in general after they are ten weeks old is bad management; for his account in this respect is uniform, that of nine or ten having paid as much a week as those of twelve or thirteen, and, although a calf of six weeks old may suck nearly as much milk as a calf of twelve weeks old, yet for the first month or five weeks the quantity is considerably less, and the advantage of their infancy is doubly as valuable to nine as it is to twelve weeks. There can be no doubt but that the profit of this system of fattening depends materially upon the quickness of return.

6050. *In some districts, barley-meal, finned boiled into a kind of jelly and similar articles, are given to calves in the course of fattening;* but the methods above described are greatly superior although it must be allowed that they may sometimes be considerably more expensive.

6051. *The art of fattening calves for the butcher is practiced in the parish of Ayndale or Strathaven, with a degree of success, according to Aldon, which has had no parallel in Scotland.* The superior excellence of the Strathaven veal has long been proverbial in the Glasgow and Edinburgh markets, where Strathaven veal and that of the best quality have become synonymous terms. The mode of feeding them is easy and natural. They are fed on milk, with seldom any admixture; and they are not permitted to suck their dams, but are taught to drink the milk from a dish. The only art used in feeding calves in the vicinity of Strathaven is, to give them, after the first two or three weeks, abundance of milk to keep plenty of dry litter under them, in a place that is well aired, neither too hot nor too cold, and to exclude the light, as they are apt to become too sportive when exposed to much light. If a calf becomes coarse a little basin or motion broth will give it ease and if it begins to purge, a small quantity of the resinous used in coagulating milk will cure the disease. (*Aldon's Dairy Book* p. 68.)

#### SUMMARY 6. Fattening Horned Cattle.

6052. *The fattening of cattle demands considerable and constant attention, and the grand object is to fatten quickly.* An animal when in a state of rearing may be considered as a vessel open at both ends, in which the supply and the waste being nearly equal it can never be filled. Fattening an animal may be considered as an attempt, to fill the vessel, and this can only be done by excess of supply. The waste being the same as before, this excess must be great. If it is not so, the vessel may be filled to a greater height than before without ever becoming full. An important hint might be taken from this simile by many farmers, who know little of the difference between feeding and fattening. We have known cattle, sheep, and swine kept for months, and fed with a view to fattening them, without their gaining a pound of meat.

6053. *The food on which cattle is fattened in summer is grass, commonly on pastures, but, in a few instances, cut and consumed in feeding-houses or fold-yards.* In winter by far the greater number are fatted on turnips, along with hay or straw, oil-cake, carrots, potatoes, and other articles of food, are used occasionally and in particular districts, oil-cake chiefly for feeding the larger animals but few comparatively are fatted on any of these without the addition of turnips of one or other of the varieties generally cultivated. A considerable number of cattle are also fatted on the offals of distilleries, when distilling from corn; a source of supply the frequent interruption of which has been much felt in those situations where the soil does not permit the extensive cultivation of turnips. It is seldom or never the practice of the best managers to fatten cattle with roots or other winter food on the field, during that season; but to confine them to houses or fold-yards, where they are well littered, regularly fed, not liable to be disturbed, and sheltered from the inclemency of the weather and where the manure they make is an object of very considerable importance, and of much greater value than if it were dropped at random over a whole field.

6054. *The age at which cattle are fattened depends upon the manner in which they have been reared; upon the properties of the breed in regard to a propensity to fatten earlier or later in life; and on the circumstances of their being employed in breeding, in labour for the dairy or reared solely for the butcher.* In the latter case, the most improved breeds are fit for the shambles when about three years old, and very few of any large breed are kept more than a year longer. As to cows and working oxen the age of fattening must necessarily be much longer, and in most instances the latter are put up to feed after working three years, or in the seventh or eighth year of their age. In general, it may be said, that the small breeds of cattle are fatted on pastures, though sometimes finished off on a few weeks' turnips, and that large cattle, at least in the north, are chiefly fatted in stalls or fold-yards, by means of turnips, and the other articles before mentioned.

6055. *Shed-feeding is the most common, and, when judiciously conducted, probably the most eligible method, in equipping the cattle themselves, the economy of food, and the expense of farm buildings.* The small shed and fold-yard, called a *henned* (6051), are used only for the larger breeds; but they do not

well calculated for an extensive system of fattening by those who do not breed, but purchase stock every year from different parts. (*See B. 274, art. 49.*)

6854. *The two great points in feeding animals to profit, according to the author of the Farmer's Calendar, are, regularity, and a particular care of the weaker individuals.* On the latter account there ought ever to be plenty of trough or rack room, that too many may not feed together in which very common case the weaker are not only trampled down by the stronger, but they are worried, and become cowed and spiritless, thus which there cannot be a more unfavourable state for thriving; besides, these are ever compelled to shift with the worst part of the meat. This domineering spirit is so remarkably prevalent among horned cattle, that he has a hundred times observed the master-beasts running from crib to crib and absolutely neglecting their own provender for the sake of driving the inferior from there. This is, much oftener than suspected, the chief reason of that difference to be visible in a lot of beasts, after a winter's keep. It is likewise, he says, a very common and very shameful sight in a dairy of cows, to see several of them poor and wounded in a dozen places, merely from the instruction of the owner, and the neglect of tending the worse of those that hurt. The weaker animals should be withdrawn and fed apart; and in crib-feeding in the yard, it is a good method to tie up the master-beasts at their meals.

6857. *Fattening cattle.* Donaldson observes are usually put to grass in May or June, according to the season and situation in regard to climate. The period necessary for fattening an ox for the butcher depends on several circumstances as the condition he was in when put to grass, the nature of the pasture and many others; but, in ordinary cases, an ox will be completely fattened in three months. There is, he says, one method of fattening connected with the grazing system, that the farmers in England are, from the superior excellence of the climate, enabled to adopt with success, which can never be attempted with propriety in Scotland. It is very common at the close of the grass season, when the fattening stock happen not to be fully in condition for the butcher, to render them so, by giving them hay two or three times a day in the field, or in hovels erected for the purpose, into which they have access at pleasure.

6858. *When turnips are employed for the purpose of fattening cattle, especially if they are put up to the stalls in proper condition which covers the season of the year (November) must, with ordinary attention, always be the case from ten to thirteen weeks is fully sufficient to render them fit for the market.*

6859. *The fattening of cattle with grass may in some respects, be considered as a branch of the distillery business; but yet there are some instances where the owners cultivate farms practice it with a double view—the obtaining of a profit on the sale of cattle and the acquisition of a valuable treasure of useful manure. Adam, the renter of the farm of Mount Nod near Strathnam in the county of Surrey erected a very complete building for the purpose chiefly of fattening cattle on grass. In this building might sometimes be seen several hundred head of cattle.*

6860. *The method of fattening cattle with oil-cake, corn, cut chaff &c. is practised in many of the English counties, with a degree of success sufficient to warrant farmers in other parts of the island to follow the same practice. The cattle are commonly put up to fatten at the end of the grass season. The usual allowance of oil-cake, after it is broken in a large mortar, or in the fruit districts, in a cyster mill is about half a peck per day one half in the morning and the other in the evening to which is added hay and in some cases ground corn that is, sets or butter of inferior quality and cut straw proverbially "chaff." As bullocks fattened in this manner get regularly fat, and sometimes six months a day it is sufficiently evident that, although it may be, upon the whole an expensive mode of fattening, yet it must be both expeditious and effectual.*

6861. *Beest's establishment for fattening cattle at Brentford is one of the most extensive in the neighbourhood of London. It was formed for the purpose of consuming on the spot the grain and wash of the extensive distillery of that town. The building is 210 feet long, and 180 feet wide; and calculated to contain 600 head of cattle. It is 6000 ft. The walls are built 10 feet high with 50 windows on each side and 8 windows at each end, not glazed, and five glazed skylights in the roof. The roof forms one ridge, and the entire part of it is covered with tiles, so numerous as to have the appearance, on first inspection, of a range of six feet, the centre of which is paved with plates of cast-iron is continued round the whole building and between every two rows of cattle are passages, of the same width and description. The whole is lighted by thirty glass lights. The cattle stand in stalls seven feet and a half wide and the space from the manger to the gutter behind the cattle is but ten feet. The gutters have an inclination to one end, and there are slender ground drains having similar inclination into which the liquid from the gutters runs through iron gratings. There is a common manger which extends the whole length of each row of cattle, the bottom of which is on a perfect level. The portion of this manger contained in every double stall has a second bottom, with two ends let into it, the second or upper bottom descending to within three inches of the bottom seen to the whole manger. In the upper trough or flume and which, in length, occupies about half of the length of the portion of the manger belonging to each stall, a put five grains, or other solid food, the common manger being for the re-*

ception of the wash or other liquid food or drink. The immense quantity of wash produced by the distillery is kept in cisterns or tanks above the level of these mangers, and in different parts of the premises, but each pipe from these tanks is conducted under the surface and communicates with each of them so that by turning back the whole of the cattle in any one of the ranges are enabled to sip wash. This article serves as both a food and drink, as it contains the finer particles of the ground malt, and the greater part of the barley meal used in the mashing process. The grasses are laid in deep pits about twelve feet square, and ten or twelve feet deep, some pits are covered at bottom then at top, and wash is kept at a distance, and when the grass is trodden in, and mixed like the case of horse dung recovered with road stuff to exclude the air, and protect them from the weather. Little or no water is used, and neither grass food nor hay must be over it. Oil-cake is used, but not always. It being found that rough clover chaff mixed with the grain and wash will suffice to any extent.

6862. *This building though erected at great expense is very successful, and far from noxious. It is much so said to winter the swiftness of the roof and, especially, very impeding the view from its great height. Within the view is strictly destroyed by unsightly humanlike posts, three feet high, of which there are little or none. For one third part of the cost an equally useful, and much handsomer structure might have been erected. It has never paid profit to its owners who, if they could sell their wash and grass at the present market price, calculate that their profits would be considerably greater than by consuming it on the premises.*

#### SUBJECT 7 Management of Cows kept for the Dairy.

6863. *Milk cows are kept for the manufacture of butter and cheese for the suckling of calves for the butcher, and for the immediate use of the milk.*

6864. *The kind of cows used by the dairy-women who supply the London market is chiefly the Holsteins, a variety of the short-horned breed, with large carcasses and short horns. They are bred chiefly in Yorkshire and Durham; but in part in most counties. The Edinburgh dairies are supplied by short-horned cows from Roxburghshire, and other pastoral districts in the south of Scotland. For private dairies the variety bred in Ayrshire (*See 6864*) have a decided preference, as giving a rich milk and large proportion of butter; and the cheese made from the milk of this breed, known as Dunlop, is decidedly celebrated. In Lancashire, the native long-horned breed is said, in the Report of that county to obtain the general preference, but in Hodgman's dairy at Coton, in the same district, it was found that a short-horned cow upon an average of twelve months, will yield nine quarts of milk in the day, and four and a half pounds of butter in the week, and a long-horned cow gives eight quarts of milk in the day and four pounds of butter in the week, for the same period. The cows of both kinds had constantly the same kind of food, but, in order to have the clear result, the quantity of food consumed by each cow of the different breed should have been fully ascertained. The produce of milk and butter is on the side of the short-*

3 U

horned sort but it is not ascertained whether the best balance is in favour of the short or long-horned. (*Memorial* May 561.) The Guernsey breed is valued by some for the richness of the cream and butter; but, both for the dairy and butcher, it is very unprofitable.

6565. *Where butter is the principal object*, such cows should always be chosen as are known to afford the best milk and cream, and in the largest quantity of whatever breed they may be. But the weight of butter to be made from a given number of cows must always depend on a variety of contingent circumstances, such as the size and goodness of the beasts, the kind and quantity of the food, and the distance of time from calving. As to the first, it need scarcely be mentioned that a large cow will give greater store of milk than one of a smaller size, though cows of equal size differ as to the quantity of cream produced from the milk of each. It is, therefore, on these cows whose milk is not only in large abundance, but which, from a peculiar inherent richness, yields a thick cream, that the better dairyman is to place his chief dependence; and where a cow is deficient in either of these, she should be parted with and her place supplied by one more proper for this use. As to the second particular, namely the kind and quality of the food, those who would wish to profit by a dairy ought to provide for their cows hay of a superior goodness, to be given them in the depth of winter, and then in an unlimited degree, that they may always find till they are perfectly satiated; and, when the weather will permit, the cows should be indulged with an outlet to marshes or low meadow grounds, where they may feed on such green vegetables as are present, which is far preferable to the practice of coining them the whole day on dry meat, will enable them to yield greater plenty of milk, and will give a fine yellow colour to the butter even in the winter season.

6566. *In the vale of Buckinghamshire and Oxfordshire*, very great numbers of cows are kept for the purpose of butter. These fertile lands maintain a breed of large cows, which yield great stores of milk, so that it is an uncommon circumstance for one farmer to keep a herd of fifty or sixty, and to collect a quantity of cream sufficient to fill a barrel-churn of sixty gallons in a week. The butter made from this cream is sold by the farmer or dairyman to persons who make it their business to purchase this article at a stated price from Michaelmas to Lady-day, and at an inferior rate from Lady-day to Michaelmas. The butter thus collected is sent to London every week in waggons. It is consigned to the dealers, who retail it to the consumer, and so small profit from this trade accrues to the waggoner and the butter merchant. This butter is mostly made up in lumps of two pounds each, and for that reason it has obtained the name of lump-butter. Its flavour is peculiarly sweet and agreeable, which is chiefly owing to the goodness of the pasture whereon the cows are fed for this intrinsic merit could in vain be sought for in butter made from ordinary pastures, how great soever may be the skill of the dairy woman. Though the grass should be equally luxuriant, the cows of the same breed and the cream in like abundance yet would a decided preference still remain in favour of the vale-fed cows, for, as a fattening beast on rich land will thrive much quicker than on thin soil, though the herbage be shorter on the former than on the latter ground, so will cows give a larger store of milk, and that of a more nutritious quality when fed on deep fertile meadows, than if depastured on those of inferior goodness or quality.

6567. *Though butter has long been held in the highest estimation* and great quantities are manufactured in Cambridgeshire and the adjoining counties. The Cambridge butter is sent in small pans: it has an additional quantity of milk mixed with it, to insure its keeping for ten days or a fortnight, and is generally perfectly free from any rancid taste. Yorkshire, Lancashire, and other large bounding counties, where the land is rich and fertile, likewise supply large quantities of butter, which is salted and put into tubs for the southern markets.

6568. *Where cheese is the principal object*, the management in respect to the cows must be the same.

6569. *When the object is the suckling of calves*, the farmer should provide himself with a breed of cows suited to the quality of his land. Where the farm abounds with fertile pastures, watered with wholesome streams, and not far distant from the yard, so that the cows may be turned immediately out of the suckling house upon their feed, the benefit will be in every respect superior to what can be expected from an sterile farm, or where the grass land is in a small proportion to the ploughed for in the latter case, the cows must depend for their sustenance chiefly on artificial fodder, such as clover, rye grass, turnips and other roots and herbage.

6570. *The cow-house* should be of a size adapted to the number of the beasts. Each cow should be driven into the house at suckling time, and her head confined in a proper manner having some fodder lying constantly before her and a space left between every beast. When they become accustomed to this kind of restraint, they will without any trouble come into the places destined for them, when the calves may be suckled with the greatest ease and facility.

6571. *The time cows should become dry before their calving* is not agreed on, some contending that they may be milked almost to the time of their dropping the calf without injury, while others maintain that it is absolutely necessary that they should be laid dry from one month to two, both for the advantage of themselves and their calves. It is probable that much in this business must depend on the manner in which they are kept, as when well fed they may be continued in milk till within a week or two of their calving without suffering any injury from it; but in the contrary circumstances it may be better to let them run dry for a month, six weeks, or more, according to their condition, in order to their more fully recruiting their strength. It appears not improbable, but that the longer the milk is continued, the more five the cows will be from indurations and other affections of the udder, which is a circumstance deserving of attention. Where only one or two cows are kept for the supply of a family it is likewise useful to know that by good feeding they may be continued in milk without any bad consequences till nearly the time of calving.

6572. *Cows sometimes slip their calves before they are sufficiently grown*. Where this occurs, it is essentially necessary to remove such cows immediately from the cow yard, or from mixing with the other cattle, for a few days. But where cows are much subject to such accidents, it is the best method to get quit of them as soon as possible, as they will seldom turn out profitable afterwards.

6573. *Cows should be kept constantly in good condition*, as where they are ever suffered to become very lean, and that in the winter season, it is impossible that they can be brought to afford a large quantity of milk, by getting them into perfect condition in the summer months. Where cows are lean at the period of calving, no management afterwards is ever capable of bringing them to afford for that season any thing near the proportion of milk that they would have done if they had been supported in better condition during the winter. Food of the most nourishing and succulent kinds should therefore be regularly given in suitable proportions in the cold inclement months and the animals should be kept warm, and well supplied with pure water. Some advise their being cleaned by combing and other means, but this is a practice which, though useful in making them yield their milk more freely, can perhaps seldom be advantageously employed on an extensive scale.

6574. *When the time of calving is calculated*, an account should always be kept of the time when each cow takes the bull, that she may be dried off at a reasonable distance of time before the expected term of gestation be completed. The usual time when the cow is dried off is two months before her calving, when she ought to be suffered to lie quiet, and should not be brought up with the other cows at milking or suckling-time. According to some, if a cow be continued in milk nearer to the time of calving than the period above stated, it will not only greatly injure her future propensity by rendering it weak and stunted, but will also have an ill effect on her own health; while others, as we have seen (6571) consider ten days or a fortnight as sufficient. When a cow is four months gone with calf, this fact may easily be ascertained by pressing upon her off-shank, when the calf will be felt to kick against the head.

6575. *Cows may be known to be near the time of calving* by springing at the udder or at the bearing. By springing at the udder is meant the collection of liquid in the bag, which a few weeks before the time

of gestation is accomplished, assumes, in some degree, the appearance of milk, and may be drawn from the teats. To spring at the bearing, is when this part is more than ordinarily large and distended. Heifers are said to spring soonest at bearing and old cows at the udder. Some cows are peculiarly given to abortions; and where this happens, they should never be continued long in the herd, as being unlikely to yield any considerable degree of profit to their owners.

6876. *Cows which are expected shortly to calve* ought to be lodged at night in a large convenient out-house, or some other place for a week or two previously to calving, as it may be the means of saving the life of the calf, and perhaps that of its dam. For when a calf drops in the yard or field under such circumstances, the hazard of its perishing through the inclemency of the weather is very great, and it may considerably endanger the life of the cow. But if, from inattention or other causes, the creature should catch cold by calving abroad in sharp winter nights (which may be perceived by a refusal of her food, and by her trembling joints) she ought immediately to be driven into a warm shed, together with her calf and fed with sugar-sops and ale, and with the best and sweetest hay and should not be suffered to drink any cold water. By this treatment she will mostly recover in a few days but should the disorder hang about her teats composed of aromatic cordial substances may be given.

6877. *A milk cow is in her prime at five years old*, and will generally continue in a good milking state till ten years old or upwards; but this depends greatly on the constitution of the animal. Some cows, like other animals, exhibiting marks of old age much earlier than others.

6878. *Cows of large size* yield great store of milk when turned on pastures where the grass is in sufficient abundance, or fed with a constant supply of such food as from its succulency conduces much towards the nutriment of the creature, and enables her to give large quantities of milk, such as turnips, grain, garden vegetables, &c. But as these large cows require a vast ample provision than would fall to their share on the generality of farms, it would seem that they should not be kept by those farmers whose land is not of the most fertile kind, for, on ordinary keep, a small cow will yield a fairer profit than one of the Yorkshire or Staffordshire breed, who, having been bred on the best kind of land, would be starved where a Scotch or a Welsh cow would find an ample supply of food.

6879. *Those who are desirous to keep few cows*, either as calf-sucklers dairymen or milk-sellers, should always provide a bull to run in the herd, to obviate the perpetual trouble of driving them perhaps a mile or more to the bull, and in order to prevent the loss and inconvenience of their becoming frequently barren. One bull will generally be sufficient for twenty cows. These animals are in their prime at two years old, and should never be suffered to continue longer in a state of virility than to the fifth year; as after that time, bulls which before were gentle and lay quiet in the cow pastures, are mostly apt to contract vicious dispositions and become very unmanageable. Whenever this happens, they should be immediately castrated. In the principal town dairies of Scotland such as Edinburgh Glasgow &c. the cows are never allowed to take the bull, but are sold off after being kept a year or less, to the butcher and fresh cows bought in their place. This is one very remarkable difference between the management here and in the town dairies of England.

6880. *For feeding of stabled cows* the following directions are given to the cow feeder in an improved dairy establishment near Farnham in Surrey.—"Go to the cow stall at six o'clock in the morning winter and summer give each cow half a bushel of the field beet, carrots, turnips or potatoes cut at seven o'clock, the hour the dairy maid comes to milk them, give each some hay and let them feed till they are all milked. If any cow refuses hay give her something she will eat, such as grain, carrots, &c. during the time she is milking, as it is absolutely necessary the cow should feed whilst milking. As soon as the woman has finished milking in the morning turn the cows into the airing ground, and let there be plenty of fresh water in the troughs. At nine o'clock give each cow three gallons of a mixture composed of eight gallons of grain and four gallons of bran or pollard when they have eaten that, put some hay into the crib. At twelve o'clock give each three gallons of the mixture as before. If any cow looks for more, give her another gallon; on the contrary if she will not eat what you give her take it out of the manger never at one time feed a cow more than she will eat up clean. Mind and keep your mangers clean, that they do not get sour. At two o'clock give each cow half a bushel of carrots, field beet, or turnips look the turnips, &c. over well before you give them to the cows as one rotten turnip, &c. will give a bad taste to the milk and most likely spoil a whole dairy of butter. At four o'clock put the cow into the stall to be milked feed them on hay as you did at milking time in the morning ever keeping in mind that the cow whilst milking must feed on something else. At six o'clock give each cow three gallons of the mixture as before. Rank them up at eight o'clock. Twice in a week put into each cow's feed, at noon a quart of milk dust."

6881. *Directions to the dairy-maid*.—"Go to the cow stall at seven o'clock take with you cold water and a sponge and wash each cow's udder clean before milking; downe the udder well with cold water winter and summer as it braces and relieves heat. Keep your hands and arms clean. Milk each cow as dry as you can morning and evening and when you have milked each cow as you suppose, dry begin again with the cow you first milked and drip them each for the principal reason of cows failing in their milk is from negligence in not milking each cow dry particularly at the time the calf is taken from the cow. Suffer no one to milk a cow but yourself, and have no gossiping in the stall. Every Saturday night give in an exact account of the quantity of milk each cow has given in the week." (*Farm. Mag.* vol. xv p. 314.)

6882. *Harley's dairy establishment at Glasgow* has been celebrated since 1813. The object of the proprietor who is engaged in various extensive concerns, is to supply the public with new milk free from adulteration, and to have the cow-house cows, and milk kept in a more cleanly state than by the usual mode.

6883. *Harley's cow-house* is fitted up upon a new construction. The cattle stand in rows, twelve in a row, across the house, head and head, and tail and tail alternately; there is passage behind for cleaning, and one in front for feeding. In front of each cow is a wire grating, hung like a window, which lifts up when giving the milk food and cleaning the crib, and is put down when they get hay &c. The convenience for washing the teats following the milking, ventilating the house, &c., give peculiar advantages to the establishment, which may be summed up in the following items.—The health of the cattle, the prevention of the diminished disease from fire, there being no hay-stuff above the cattle; the preservation of the underwood; and the freedom of the walls. The house is regulated by thermometers. A circulation of air can be produced as to keep the cattle comfortable in the hottest weather by which their health is promoted. The ventilation also prevents the fever from visiting; enables the cows to shake their heads as their heads are allowed to escape, instead of being thrown back upon the food, as is the case when their heads are placed opposite wall. It is well known that milk easily takes a taste from any other substance; of course, if the cow house is filled with hay, the milk while passing from the teats to the milk pail must derive the taste it may stand in the house, will be impregnated with the food atmosphere.

6884. In feeding and preventing the disease from fire made many experiments, and by the mode he now follows, the cattle feed and milk better than by the ordinary process; and the milk has no taste from any other substance.

6885. The arrangement for milking, enables the cow to be clean, rather, and also prevents fraud; and the mode of lock-

ing up the milk, and at the same time of admitting air prevents adulteration by the milkster. The cows are not turned out to milk as in London.

6886. *The state of cows* for some time back has been very variable eleven English quarts each per day but both quality and quantity depend much upon the kind of food. Harley gives decided preference to the Ayrshire breed of cows. They are brought chiefly in country carts, either sent calves, or a few weeks before calving, and never turned out till they go to the butcher.

6887. *The food of the cows during summer* consists of cut grass and green barley mixed with old hay and during winter Harley uses a good quality turnips and potatoes, all of which are at hand and mixed with cut hay and straw; also green and chaffery meal when these can be got.

6888. *When time to serve new cows* which supplies the demand, part is put to the milk-house till next day when the selected milk is sold at half price and the cream sold at 1s. 6d. per quart. When any cream is left, it is put in a churn, and made into butter once a week or fortnight.

6889. *A note of regulations* has been adopted, for the purpose of feeding, milking, carrying the cattle, cleaning the house, &c. Each person has a key and a key chain for the cows, the cow-creeper, and a key and pull for the house, which is used to lock the door twice a day.

6890. *The cleanly state of the cattle and house* makes it a treat for visitors to see the establishment; and the way the yards and milk-houses are kept has made some people fond of milk who formerly were disgusted at it, thus the manner in which many towns dairies are conducted.

6961. The advantage of irrigating grass lands with the cow's urine almost needs no saying. Last season some small fields of old grass were cut on the 12th, containing fifteen inches in length at year's ending, and the result was that the crop was of a peculiarly healthy nature and was applied to the same purpose with considerable advantage.

6962. The advantage of the system to the owner of the cattle is shown by the following statement, in Mr. Barker's own words: but the benefit of it almost equals the positive result to the community as a large, particularly to children, it is not only to increase —

To the general health of the cattle by vaccination

To the production of a disease called grass sickness, when fed on grass, by eating young and wet grass

To the production of galling when feeding on bracken or potatoes, &c.

To secure the amount of feeding, by improved means of feeding, &c.

Herefordshire, and as they are only worked a few years it does not seem desirable to be at any great expense in their training. The Roman practice, in this particular, may deserve imitation. (98.)

9813. *Working oxen taken down to a house* are generally cut down to their places by the same sort of fastening used for cows, (fig. 865.) in which their neck has free play between two upright spars but in

863

some establishments a ring of a particular deer skin (fig. 864.) is used, to which they are tied by a halter attached to a head strap or bridle. The ring is generally screwed into the front of the manger or eating trough. The cattle fastening used in Devonshire is a wooden bow put on their necks and fastened to a round post. The bow consists of two pieces, the yoke, which has two slits terminating in round holes, and the bow, which is made of split ash, and has a knob at each end. These knobs being put through the round holes the elasticity of the bow forces it along the slit and prevents it from returning.

9814. *Harness for labouring cattle* is of three kinds, that for bearing as saddles some sorts of oxen yokes, that for drawing or pushing as traces, breeching of saddles, &c. and that for guiding the animals, as bridles, halters, reins, &c. These articles are of considerable expense but when taken care of kept dry, and the iron joints are occasionally oiled, occasionally, they will last a long time. In making all harness for beasts of labour great care ought to be taken to avoid superfluous materials which only encumber and ornaments which only add to the expense. The London harness is much too heavy for agricultural purposes, that of Warwick or Newcastle is much more light and sufficiently strong.

9815. *The most approved kind of harness* for the ox is little different from that of the horse, except in the shape of the collar. In many places however, and especially on the Continent, the ox draws solely by the withers by means of what is called a yoke and bow (fig. 867.)

867

9816. *The shoeing of oxen* is a practice which is yet far from being performed in a perfect manner. Clark says, that in many parts of France where the ox is used for draught, it is sometimes necessary to employ eight shoes, one under each nail, or four one under each external nail, and sometimes only two, one under the external nail of each fore foot. In this country two pieces or shoes to each foot are generally made use of being mostly fixed on, especially in the northern districts, with the ox or four large-headed nails to each shoe. They are fitted on in a similar manner to those of the horse. But, as the shoes of these animals from the smallness of the places are so liable to break, it has been suggested to have them shod with whole shoes in the manner of the horse. But how far this practice would answer, must depend upon future trials. As there is much trouble in the shoeing

of oxen from the necessity for cauling them each time, it has been found requisite to have recourse to contrivances for shoeing them standing (fig. 868.)

868

9817. *An ox shoe* (fig. 869.) consists of a flat piece of iron with five or six stamp holes on the outward edge to receive the nails. At the side is a projection of some inches, which passing in the cleft of the foot, is bent over the hoof, so as to keep the shoe in its proper place. This projection is not, however, employed in the general practice of making these shoes.

9818. *The age at which an ox may be worked* is from two and a half to three and a half years. Some begin at two, but it ought to be for very light operations, and such as are not of long duration. The period to which the ox is worked varies from his fifth to his tenth year.

9819. *Particulars of a farmer* used to make up occasionally an ox team for the plough of four oxen and one horse as a leader, which he found did about two thirds of the labour of two horses. There are, he says, great objections to ox-teams in the plough. He has however found them useful in some sorts of farm-work, from their slow steady pace, as in scarifying, leading dung, &c. as the work suits them from its being easy and having a great deal of standing, they are, says he, much more cheaply kept than horses, and eat straw in the winter and are valuable for making dung. He never saw this practice injure their growth. They may be worked from two till five years old without any loss of time, as they grow to that age, and are then both larger and better bred than three-year old steers. He therefore recommends ox-teams for leading dung and the other odd jobs, but not to plough and harrow. If they are worked to the age of eight or ten years, it is, he thinks, a real injury to the public and an unprofitable practice to the farmer.

9820. *Buttwell* used to work his heifers moderately whilst carrying their first calves, an unobjectionable practice, provided they are well fed. Heifers are generally allowed to be good labourers and capable, if high fed, of vast exertions.

9821. *The length of time per day which an ox is fed* in the yoke varies according to the kind of labour and the age and keep of the ox. If an ox is fed on hay, oats, and some roots, he will plough four days a week; but if on straw and roots only not above three days. In the former case he is worked two whole days and two half days, and in the latter case six half days. The latter is the best plan, for which reason, where oxen are regularly worked, two pairs should be kept for each ploughman.

9822. *The most desirable breeds of oxen to work* are the Devonshire and Herefordshire varieties, which are long-lived, quick-shedding animals. Lord Somerville, who has carried the working of oxen to greater perfection than any man else, prefers the Devon breed, which most cultivators consider the quickest walkers in England. When horned cattle are only worked occasionally whatever sort of animals are on the farm, whether bulls, cows, or oxen, of good or bad breeds will necessarily be employed.

9823. *The food of horned cattle employed in labour* must be substantial. It is a great mistake to suppose they can work on straw alone. Unless they have roots added to straw in winter, and green food in summer, it will be an idle attempt to harness animals as nourished. The best and indeed the only way is to feed them well with straw, coarse hay, roots, green herbage, or pasturage, as the season and other circumstances may indicate.

866

868

SUBJECT 9. *Anatomy and Physiology of the Bull and Cow*

6921. *The general structure of the bull and cow* presents some peculiarities when compared with the horse whose anatomy having been fully explained will be taken as the subject of comparison. The ox as an animal machine displays less complexity of structure than the horse but the principal differences between the two will be found to arise from the evident intention of nature to bound the locomotion of horned cattle the limbs of the ox are therefore not found favourable to speed nor does his general mass betray that symmetrical proportion and mechanical composition that would fit it to be acted on to advantage as it requires quick motion, by the powerful muscles he evidently possesses for strength alone will not produce speed.

6922. *The skeleton of the ox is formed under the above view* and though the number of his bones differs little from that of the horse, the general form differs materially — the frontal the occipital and indeed most of the bones composing the skull are broad and extended, while to the former are appended the horns. These as we have seen (1844) partake of the nature of true bone, placed within a membranous envelopment of a mixed nature between cuticle and cartilage. The ox has no upper incisors the grass being cropped into a tuft by means of the tongue is cut off by the under incisors whereas in the horse it is nipped off by the approximation of both incisive teeth.

6923. *The vertebrae or neck bones* are the same in number and form as in the horse but from the diminished elevation of the head, and the peculiarity of attachment of the great suspensory ligament, the ox has no cervical crest. The dorsal vertebrae are thirteen with spinous processes, or without less high, and the lumbar vertebrae are six, and the sacral four the coccyx or bones of the tail are indefinite in number from eighteen to twenty five. The pelvic bones in the ox are very large and the rugged outline of the rump in little arises from the great rising of the spine of the ilium and tuberosity of the ischium the ribs are thirteen eight of them true, and five false and upon the former rest the scapulae, which do not materially suffer from those of the horse.

6924. *The fore-limb bones* are the arm and the fore-arm, which as in the horse, is composed of the radius and ulna, and bears a general resemblance to that of the horse. The knee is composed of four bones in the first row and two in the second which renders that joint inferior to that of the horse in complexity and elasticity the same holds good with regard to the hock, where the bones entering its composition are also less numerous than in the horse. The canon or shank has no splint bones attached to it, but it is lower and divides into two articular portions corresponding with the metacarpal before, and metatarsal bones behind thus, from the pattern downwards, the limb is double and ends in two separate hoofs, which present, individually a similarity of structure and design to the single hoof of the horse but less developed to the posterior part of each are appended two imperfect phalanges or claws, thus keeping a connection with the digit.

6925. *The hinder limbs* present nothing remarkable but preserve the same increased simplicity of structure with the fore.

6926. *The viscera of the chest* offer no peculiarities from those of the horse to deserve notice neither is the economy of the organs concerned different.

6927. *The viscera of the belly of the ox* have some special ties, the principal of which consist in the digestive organs, which differ in form, structure, and economy in some essential particulars, from the same system in the horse.

6928. *The ox has four stomachs* in which formation the goat, sheep, camel and deer participate. As it is necessary to these animals should collect much herbage for their support and as it would fatigue and keep them too long in motion to gather and masticate such a quantity at the same time, so a peculiarity has been made for them, by which they first hastily collect their food, pass it into a reservoir and afterwards commence the mastication of it at their leisure.

6929. *The first stomach, rumen, or paunch* is a very large membranous and muscular bag, principally occupying the left side, and extending when full from the middle of the ribs to the haunch into which the unruminated food is received consequently it is the over distention of this which occasions the malady called bloat it is in this stomach also that the concretions called hair balls are found. It presents numerous processes to assist in the retention of the food.

6930. *The second stomach* called also reticulum would appear as a globular appendage to the paunch merely were it not for its peculiarity of structure, which resembles the cells of the honey comb, and which is well known to the eaters of tripe. The oesophagus, or gullet, enters at the junction of this with the first stomach, and is continued in the form of a muscular ridge, or segmental tube along the line of junction between these two stomachs, which is thence continued into the *third-stomach*. In the horned ruminants the second stomach is exclusively designed as a reservoir for water and is capable of holding and preserving a vast quantity of it. A little of this water is passed up as wanted, to be mixed with the dry matters (chewed during mastication). In the deserts of Arabia where water is met with only at long distances, this reservoir is peculiarly advantageous to the camel and dromedary, and the Arabian travellers, when famishing for water as themselves frequently at the expense of their camels, by killing of which, and taking out this stomach they find a supply.

6931. *The third stomach* is named after its foliated structure *manyplies* there are about eighty or ninety of these septa or folia which are covered with cuticle, in common with the two former stomachs, by which some resemblance is kept up between the digestive processes of the horse and ruminants. By the comparative insensibility of these stomachs they can also bear potent medicines, which would be destructive to the Carnivora. By this curious extension of surface the unruminated food is applied and resopped to the sides of the bag to be acted upon in its early stage of digestion.

6932. *The fourth stomach* called also the *red bag*, abomasum, folliculus, and ventriculus intimus has, as about two feet nine inches long in an ox, and resembles the simple digestive stomach of the Mammalia. It is in this stomach that the pulsatious mass of the chyme undergoes a more perfect animalisation by being mixed with the gastric fluid, which appears to be wholly secreted here and thus it is that this stomach only produces rumen. The red bag to increase its secreting surface has likewise about nine longitudinal plies on each side with an intervening rugose structure.

6933. *Ruminatio, or chewing the cud*, is the process whereby the ruminant animal having collected their food, and having passed it into the paunch, with little or no mastication on or expense of saliva begins a new operation. The paunch being full the animal is stimulated to seek rest and quiet, and he usually lies down. The paunch begins now to exert its extraordinary powers of separating a portion from the contained mass, and to return it into the mouth where it undergoes a complete mastication and mixing with the saliva. It is then again passed down the throat but instead of again entering the first stomach, the muscular gullet forms itself into a tube, and carries it at once into the third stomach where it has long to undergo a further change, it is passed into the red bag, or fourth stomach to undergo a further solution by means of the gastric fluid, preparatory to its being converted into nutriment under the name of chyle.

6934. *The intestines of the ox* have not their divisions into great and small so well marked as in the horse, yet the tract is very extended, to admit of a perfect separation of all the chylous particles. In the intestines of the horse it has been shown (8408) that much of the digestive as well as the operative process goes on but the chylous mass is more broken down in the stomach of a cow than by the united forces of the stomach and intestines of the horse. Grass, containing less organic molecules than grain requires to be minutely acted on to afford nutriment and thus the well fed horse, after having been sufficiently nourished, passes off dung containing much of the original principles of his farinaceous food, and which forms excellent manure while that of the ox, becoming almost wholly decomposed and nearly fluid, is very inferior for that purpose.

6928. The *blow of the sea* is large, and presents a gall bladder which that of the horse does not. This gall bag is furnished by several hepatic ducts leading into the neck of the gall duct. By the existence of a gall bladder the bile is evidently more concentrated but it is difficult to understand why this should be necessary to the ruminants and not to the horse.

6929. The *pancreas of the sea* is of a lozenge form. The *spleen* is very large, and is placed on the left side of the stomach. The biliary and pancreatic ducts unite together. The principal fold of the *oesophagus* is very large, and includes the four stomachs, and part of the intestines. The *renal capsule* are flat and telodermic. The kidneys are lobulated.

6930. The *organs of generation* in the cow differ but little from those of the mare and other Mammalia. The penis of the bull is more pointed and taper than that of the horse. The vesiculae seminales are wanting, but have a small ligamentous bridge instead. The prostates are two.

#### SUMMARY 10. Diseases of Horned Cattle.

6931. Cattle are subject to some very dangerous diseases, but as their life is less artificial, and their structure less complex, they are not liable to the variety of ailments which affect the horse. The general pathology of the horse and the ox being little different, the fundamental rules for veterinary practice, and the requisite medicines, when not particularised, will be found in the *Veterinary Pharmacopoeia*, already given. (6941)

6932. *Mild fever* pentos or pentosis. Cattle sometimes appear affected with heat, redness of the nostrils and eyelids, they refuse food, are dull & acute and stale with difficulty and the urine is high coloured. These symptoms are often aggravated every other day giving the appearance of an intermittent affection. The complaint is often brought on by over-driving in very hot weather occasionally by pushing their fattening process too fast. If there be no appearance of malignancy and the heaving be considerable, bleed, and give half an ounce of nitre in a drink night and morning but unless the weather be cold do not hose the animal.

6943. *Inflammatory fever* is called, among farmers, cow-leeches, and graziers, by the various names of black quarter, evil-smell, quivering of blood, joint mairan, &c. striking in of the blood, &c. Various causes may bring this on. It is sometimes epidemic and at others it seems occasioned by a sudden change from low to very full keep. Over-driving has brought it on. No age is exempt from it, but the young often have it than the mature. Its inflammatory stage continues but a few days, and shows itself by a dull and heavy countenance, red eyes and eyelids, the nostrils are also red, and a slight mucous flow from them. The pulse is peculiarly quick, the animal is sometimes stupid, at others watchful, particularly at first, and in some instances irritable. The appetite is usually early lost at the end of the second day, and the dung and urine either stop altogether or the one is hard, and the other mud. About the third day a critical deposit takes place, which terminates the inflammatory action, and it is to the various parts on which this occurs that the disease receives its various names. The deposit is, however, sometimes universal, in the form of a bloody suffusion throughout the whole skin. In others, swellings form on the joints, or on the back or belly, and in fact, no part is exempt from their attack. Sometimes the animal swells generally or partially and the air being suffused under the skin, ripples to the feel. After any of these appearances have come on, the disease assumes a very malignant type, and is highly contagious.

6941. *Treatment of inflammatory fever*. Before the critical abscesses form or at the very outset of the disease, bleed liberally and purge also give lilacum a fever drink (6579) If however the disease be not introduced in this early stage, carefully abstain from bleeding, or even purging, but instead, throw up clovers of a quart and salt to copy the bowels, and in other respects treat as detailed under malignant epidemic. (6496.) It may be added, that four drachms of auric acid in three pints of oak bark decoction, given twice a day, has proved useful. The swellings themselves may be washed with warm vinegar both before and after they burst. The cowhouse should be fumigated daily.

6942. *Catarrh or influenza* in cattle, also known by the name of *fever*, is only a more mild form of the next disease. Given in this mild form it is sometimes epidemic, or prevalent among numbers, and is enhanced by being local. Very stormy wet weather changing frequently and greatly also in its temperature, are common causes. We have seen it brought on by change of food from good to bad and from too close pasturage. It first appears by a defluxion from the nose the nostrils and eyelids are red, the animal heaves or is tickled up in the flanks, and on the third day he loses the coat. There is a distressing and painful cough and not unfrequently a sore throat also in which case the beast almost invariably holds down his head. The treatment does not at all differ from that directed under the same disease in horses. (6134.) Bleeding only the first two days, carefully sheltering but in an open airy place and hithering well up.

6943. *The malignant epidemic influenza* is popularly called the *measles* or *peel* and has at various times made terrible havoc among cattle. Ancient history affords ample proof of its long existence, and by the accounts handed down, it does not seem to have varied its type materially. In 1757 it visited Britain, producing extreme fatality among our kine. From 1710 to 1714 it continued to rage on the Continent with unobscured fury (*Lencier's Dictionnaire Historique de Boeille Feste*). The years 1730 and 1731, and from 1744 to 1746, witnessed its attack, and produced many written descriptions of it, among which stand pre-eminent that of Sauvages, the celebrated professor of medicine at Montpellier. The British historian of the maledy in 1757 effected an excellent work from the pen of Dr Lynam, a physician of London, which was after wards translated into several other languages.

6944. *Symptoms of the measles*. Dr Lynam describes it as commencing by a difficulty of swallowing and shaking of the ears, shaking of the head, with excessive weakness and staggering gait, which commenced a continued desire to lie down. A sanious fetid discharge invariably appeared from the nostrils, and eyes also. The cough was frequent and urgent. Fever exacerbating, particularly at night, when it usually produced quaked pulses. There was a constant scouring of green fluid dung after the first two days, which stained every thing around, even the breath perspiration, and urine were highly fetid. Little tumours or boils were very commonly felt under the skin, and, if about the seventh or ninth day these symptoms became larger, and boils or buboes appeared with a hœmorrhagic discharge of fœces, they proved critical, and the animal often recovered but if, on the contrary, the scouring continued, and the breath became cold, and the mouth dark in colour, he moribund was, mortality followed. Sauvages describes the moribund as showing itself by trembling, cold driven, nose exoriated with an acrid discharge from it, gasping after the first two days, but previous to which there was often convulsions. Great tenderness about the spine and withers was also a characteristic, with emphysema, or a blowing up of the skin by air discharged underneath it.

6945. *Dissections of those that have died of this disease*, according to Sauvages, have shown marks of great inflammation, and of a great putrid tendency, but the solid parts seldom ran into gangrene. The fluid excretions, however, always were consistently discoloured and broken down by putridity. The stomach, he says, was usually filled with undigested matter and the other stomachs highly inflamed, the gall bladder was also extensively discoloured with acid black brown bile. Gœschel who likewise dissected these subjects, described the gall as particularly profuse and intolerably fetid. According to him the whole alimentary canal, from the mouth to the anus, was exoriated and Lencier, contrary to Sauvages, found the viscera of the chest and belly, in some cases, sphacelated and gangrenous. Lencier describes the putridum as accompanied with pustular serum, and as grey as the putrid tendency, that even the milk, before it dried up, which it usually did before the fourth day, became acid.

6046. *The treatment of the murrain.* In the very early stages all eminent authors recommend bleeding; but which should not only be confined to the very early periods, as to the first two days, but also to such subjects as by their previous health and condition can bear it. The animals should be placed in an open airy place; the litter should be frequently renewed, and the place itself should be fumigated with the preventive fumigation (6082.) It has been recommended to burn green boughs with pitch as a substitute; even charcoal fires occasionally carried round the dewlap. Dr. Leyard advised the body to be washed with aromatic herbs in water but vinegar would have been better. In the early stages, saline purgatives, as from ten to twenty ounces of Epsom salts, are to be invariably used. If the scouring have already come on, still, however, purge; but with only half the quantity. An artificial purge will carry off the morbid bile and if excessive weakness do not come on, the same may be advantageously repeated. Hæmorrhages are also recommended in the dewlap. When abscesses appear they may be opened, and their contents discharged, washing the wound with brandy or vinegar if putrid moulting takes place. The emphysematous swellings or cracklings may also be opened, and the air discharged. The other essentials of medical treatment, as detailed under malignant epidemics among horses, is here applicable in every particular. When recovery takes place, it is usually a very slow process, and requires care to prevent other diseases supervening. The animals should continue to be housed and neither exposed to sun or wind for some time and the feeding should be nutritious.

6047. *The prevention of the murrain* or the prevention of its spreading, in many respects is even more important than its medical treatment. Where it has already appeared, all the out-buildings, but particularly the ox-lofts or stalls, should be daily fumigated with the preventive fumigation (6082.) and even the whole of the infected district should have frequent fires of green wood made in the open air and every such district should be put under a rigorous quarantine. The cattle on every farm should be carefully examined three or four times every day and the moment one is found to drop, he should be removed to a distance from the others. In very bad weather while it is prevalent, the healthy cattle should be housed, and particularly well fed and their pasture should also be changed. The bodies of those who die of the disease should be buried with their skins on, very deep in the earth and quick time should be strewn over them.

6048. *Phrenitis* fever or inflammation of the brain, called also *sough*, now and then, but by no means frequently attacks cattle. The symptoms differ but little from those which attack horses. The treatment must be exactly similar.

6049. *Inflammation of the lungs* occasionally occurs in cattle, in which also the symptoms, progress, and proper treatment are similar to those detailed under that head in horse pathology.

6050. *Inflammation of the stomach* sometimes occurs from poisonous matters, and in such cases, when the nature of the poison is discovered the treatment detailed under poison in horse pathology must be pursued. But there is a species of indigestion to which cattle are liable in the spring from eating voraciously of the young sprouts of wood to which some woods are more conducive than others. The symptoms are heat, thirst, uneasiness, lessened urines, quick and hard pulse, with heat and redness in the mouth and nose, the belly is hard and painful and the stools when they appear are covered with glair. When the mouth and nose discharge a serous fluid the animal usually dies.

6051. *Treatment.* Bleed at first, open the bowels by saline purgatives (6088.) After this give large quantities of trusted water and glister also largely.

6052. *The Acute fever* in cattle is also an inflammatory affection of the paunch ending in paralysis and rupture of its substance. From the frequency of its occurrence, it has become a subject of investigation with almost every rational grazier and a particular matter of enquiry with every agricultural body whence it is now very successfully treated by the usual attendants on cattle when skilful, but when otherwise, it usually proves fatal. It is observed to be more frequent in warm weather, and when the grass is wet. When either oxen, cows, or sheep meet with any food they are particularly fond of or of which they have been long deprived, — as potatoes, turnips, the different greens, particularly red clover, — they eat greedily, and forget to lie down to ruminate, by which means the first stomach or paunch becomes so distended as to be incapable of expelling its contents. From this inflammation follows and fermentation begins to take place. A large quantity of air is let loose, which still adds to the distention till the stomach either bursts or by its pressure on the diaphragm, the animal is suffocated. The situation of the breast is known by the uneasiness and general swelling of the abdomen, with the circumstances of the animal being found with such food or the presumption that it has met with it.

6053. *Treatment.* There are three modes of relieving the complaint, which may be adverted to according to the degree of distention and length of time it has existed. These are internal medicines, the introduction of a probe of some kind into the paunch by the throat; and the puncturing it by the sides. Dr. Whyatt, of Edinburgh is said to have cured eighteen out of twenty hoveed cows by giving a pint of gill to each. Oil, by condensing the air has been successfully tried. Any other substance, also, that has a strong power of absorbing air may be advantageously given. Common salt and water made strongly saline is a usual country remedy. New milk with a proportion of tar equal to one sixth of the milk is highly spoken of. A strong solution of prepared ammonia in water often brings off a great quantity of air and relieves the animal. Any of these internal remedies may be made use of when the hoven has recently taken place, and is not in a violent degree. But when otherwise, the introduction of an instrument is proper and is now very generally resorted to. The one principally in use is a species of probe, invented by Dr. Monro, of Edinburgh. Another consisting of a cane of six feet in length, and of considerable diameter, having a bulbous knob of wood, has been invented by Rager which is a more simple machine but hardly so efficacious. It is probable that, in cases of emergency, even the larger end of a common cart-whip, dexterously used, might answer the end. But by far the best instrument for relieving hoveed cattle, as well as for clystering them is Ross's sœcus apparatus, which is alike applicable to horses, cattle, and dogs. It consists of a syringe (fig. FVL. a.) to which tubes of different kinds are applied, according to the purpose and the kind of animal to be operated upon. There is a long flexible tube for giving an œsena to horses and cattle (a) and a smaller one for dogs. (b) To relieve hoven bullocks effectually it is necessary not only to free the stomach from an accumulation of gas, but from the fermenting putrescent mixture which generates it; for this purpose a tube (c) is applied to the extremity of the syringe, and then passed into the animal's stomach through the mouth (d), and set in action, the offending matter is discharged by a side opening. When the same operation is performed on sheep, a smaller tube (e) is made use of. The characteristic excellency of Ross's instrument is, that there is no limit to the quantity of fluid that may be injected or extracted. The same syringe is used for extracting poison from the stomach of man, for smothering insects, extinguishing fires, and syringing fruit trees. (Ensay. of Gen. 3d edit. 1418.) The introduction of any of these instruments may be effected by the help of an assistant, who should hold the horn of the animal by one hand, and the dividing cartilage of the nose with the other while the operator himself taking the tongue in his left hand, employs his right in skilfully and carefully introducing the instrument, the assistant bringing the head and neck into such an attitude as to make the passage nearly straight, which will greatly facilitate the operation. But when no instruments can be procured, or as cases may occur when indeed it is not advisable to try them, as when the disease has existed a considerable time, or the animal has become outrageous, or the stomach so much distended with air that there is danger of immediate suffocation or bursting in these instances the paracentesis of the maw must be instantly performed which is called *passing the maw*. This may be done with the greatest ease midway between the ilium, or haunch-bone, and the last rib of the left side, to which the thumb inclines a sharp point is dexterously used, and persons in veterinary practice should always keep a long trocar which will be found much the most efficacious, and by far the most safe, so it penetrates the air escaping certainly and quickly at the same time that it prevents its entrance into the cavity of the

6535. The liver of the ox is large, and presents a gall-bladder which that of the horse does not. This gall has 12 branches by several hepatic ducts leading into the neck of the gall duct. By the salience of a gall bladder the bile is evidently more concentrated; but it is difficult to understand why this should be necessary to the ruminants and not to the horse.

6536. The pancreas of the ox is of a longer form. The spleen is very large, and is placed on the left side of the stomach. The biliary and pancreatic ducts unite together. The principal fold of the omentum is very large, and incloses the four stomachs, and part of the intestines. The renal capsules are flat and triangular. The kidneys are lobulated.

6537. The organs of generation in the cow differ but little from those of the mare and other Mammalia. The penis of the bull is more pointed and taper than that of the horse. The testis resembles are wanting, but have a small ligamentous bridge instead. The prostate are two.

#### Summary 10. Diseases of Horned Cattle

6538. Cattle are subject to some very dangerous diseases; but as their life is less artificial, and their structure less complex, they are not liable to the variety of ailments which affect the horse. The general pathology of the horse and the ox being little different, the fundamental rules for veterinary practice, and the requisite medicines, when not particularised, will be found in the *Veterinary Pharmacopoeia*, already given. (6523.)

6539. Mild fever, putres or putrida. Cattle sometimes appear affected with cold, redness of the nostrils and eyelids; they refuse food, are dull, acute and stale with difficulty and the urine is high coloured. These symptoms are often aggravated every other day giving the appearance of an intermitting affection. The complaint is often brought on by over-driving in very hot weather, occasionally by pushing the animals to the point of exhaustion. If there be any appearance of malignancy and the breathing be considerable, blood, and give half an ounce of nitre in a drink night and morning but unless the weather be cold do not house the animal.

6540. Inflammatory fever is called, among farriers, cow leeches, and grasters, by the various names of blood quarter, joint felon, quarter evil, quarter ill, showing of blood, joint cornum striking in of the blood, &c. Various causes may bring this on. It is sometimes epidemic, and at others it seems occasioned by a sudden change from low to very full keep. Over-driving has brought it on. No age is exempt from it, but the young calves have it than the mature. Its inflammatory stage continues but a few days, and shows itself by a dull and heavy countenance, red eye and eyelids, the nostrils are also red, and a slight mucus flows from them. The pulse is peculiarly quick the animal is sometimes stupid, at others watchful, particularly at first, and in some instances irritable. The appetite is usually entirely lost at the end of the second day, and the dung and urine either stop altogether or the one is hard and the other red. About the third day a critical deposit takes place, which terminates the inflammatory action, and is to the various parts on which this occurs that the disease receives its various names. The deposit is, however sometimes universal, in the form of a bloody suffusion throughout the whole skin. In others, swellings form on the joints, or on the back or belly and in fact, no part is exempt from their attack. Sometimes the animal swells generally or partially and the air being suffused under the skin, crackles to the feel. After any of these appearances have come on, the disease assumes a very malignant type and is highly contagious.

6541. Treatment of inflammatory fever. Before the critical abscesses form, or at the very outset of the disease, bleed liberally and purge also give likewise a fever drink. (5733.) If, however the disease be not attended to in this early stage carefully abstain from bleeding or even purging but instead, throw up clysters of warm water and salt to empty the bowels, and in other respects treat as detailed under malignant epidemic. (5683.) It may be added, that four drachms of muriatic acid in three pints of oak bark decoction given twice a day has proved useful. The swellings themselves may be washed with warm vinegar both before and after they burst. The cowhouse should be fumigated daily.

6542. Catarrh or influenza in cattle also known by the name of *fever*, is only a more mild form of the next disease. Even in this mild form it is sometimes epidemic, or prevalent among numbers, or endemic by being local. Very stormy weather changing frequently and greatly also in its temperature, are common causes. We have seen it brought on by change of food from good to bad, and from too close pasturage. It first appears by a defluxion from the nose; the nostrils and eyelids are red; the animal heaves, is tucked up in the flanks, and on the third day he loses the cud. There is a distressing and painful cough, and not infrequently a sore throat also, in which case the beast almost invariably holds down his head. The treatment does not at all differ from that directed under the same disease in horses. (5684.) Bleeding only the first two days, carefully sheltering but in an open airy place, and hithering well up.

6543. The malignant epidemic influenza is popularly called the *murrain* or *pest*; and has at various times made terrible havoc among cattle. Ancient history affords ample proof of its long existence; and by the accounts handed down, it does not seem to have varied its types materially. In 1757 it visited Britain producing extreme fatality among our kine. From 1710 to 1714 it continued to rage on the Continent with unabated fury (*Lancet's Disputatio Historica de Bovilla Pestis*). The years 1750 and 1751, and from 1746 to 1748, witnessed its attack and produced many written descriptions of it, among which stand pre-eminent that of Sauvages, the celebrated professor of medicine at Montpellier. The British visitation of the murrain in 1757 elicited an excellent work from the pen of Dr. Laidlaw, a physician of London, which was after wards translated into several other languages.

6544. Symptoms of the murrain. Dr. Laidlaw describes it as commencing by a difficulty of swallowing, and itching of the ears, shaking of the head, with excessive weakness and staggering gait, which occasioned a continued desire to lie down. A stinking fetid discharge invariably appeared from the nostrils, and eyes also. The cough was frequent and urgent. Fever exacerbating particularly at night, when it usually produced quickened pulse. There was a constant scouring of green solid dung after the first two days, which lasted every thing around, even the breath perspiration, and urine were highly fetid. Little tumours or boils were very commonly felt under the skin, and if about the seventh or eighth day these eruptions became larger, and boils or buboes appeared with a lessened discharge of feces, they proved critical, and the animal often recovered; but if on the contrary, the scouring continued, and the breath became cold, and the mouth dark in colour, he informs us, mortality followed. Sauvages describes the murrain as showing itself by trembling, cold shivers, nose exoriated with an acrid discharge from it; purging after the first two days, but previous to which there was often constipation. Great tenderness about the spine and withers was also a characteristic, with emphysema, or a blowing up of the skin by air discharged underneath it.

6545. Dissections of those that have died of this disease, according to Sauvages, have shown marks of great inflammation, and of a great putrid tendency; but the solid parts seldom ran into gangrene. The fluid excretions, however, were differently discoloured and broken down by putridity. The murrain, he says, was usually filled with undigested matter and the other stomachs highly inflamed. The gall bladder was also commonly distended, with acrid thick brown bile. Goellich who likewise dissected these subjects, describes the gall as particularly profuse and intolerably fetid. According to him the whole alimentary canal, from the mouth to the anus, was exoriated, and Laidlaw contrary to Sauvages, found the viscera of the chest and belly in some cases, exoriated and gangrenous. Gamble describes the murrain as accompanied with profuse scurvy; and so great was the putrid tendency that even the milk, before it dried up, which it usually did before the fourth day became fetid.

694. *The treatment of the empyema.* In the very early stages all eminent authors recommend bleeding but which should not only be confined to the very early periods, as to the first few days, but also to recent subjects as by their previous health and condition can bear it. The animals should be placed in an open airy place the litter should be frequently renewed and the place itself should be fumigated with the preventive fumigation (688.) It has been recommended to burn given bougies with pitch as a substitute even charcoal fire occasionally carried round the place would be useful. Dr. Laidlaw advised the body to be washed with aromatic herbs in water but vinegar would have been better. In the early stages, saline purgatives, as from ten to twenty ounces of Epsom salts, are to be invariably used. If the scouring have already come on, still, however purge, but with only half the quantity an artificial purge will carry off the morbid bile and if excessive weakness do not come on, the same may be advantageously repeated, before are also recommended in the dysentery. When abscesses appear they may be opened, and their contents discharged washing the wound with brandy or vinegar if putrid discharges takes place. The emphysematous swellings or cracklings may also be opened, and the air discharged. All the other essentials of medical treatment as detailed under malnutrition among horses, is here applicable in every particular. When recovery takes place, it is usually a very slow process, and requires care to prevent other diseases supervening. The animals should continue to be housed, and neither exposed to sun or wind for some time, and the feeding should be nutritious.

695. *The prevention of the murrain, or the prevention of its spreading,* in many respects is even more important than the medical treatment. Where it has already appeared, all the out-burings, but particularly the ox lodges or stalls, should be daily fumigated with the preventive fumigation (688.); and even the whole of the infected districts should have frequent fires of green wood made in the open air and every such district should be put under a rigorous quarantine. The cattle on every farm should be carefully examined three or four times every day and the moment one is found to drop, he should be removed to a distance from the rest, and while at a distance, the healthy cattle should be housed, and particularly well fed, and their pasture should also be changed. The bodies of those who die of the disease should be buried with their skins on very deep in the earth, and quick-lime should be strewn over them.

696. *Phrenitis, fever or inflammation of the brain,* called also *sough*, now and then but by no means frequently attacks cattle. The symptoms differ but little from those which attack horses. The treatment must be exactly similar.

697. *Inflammation of the lungs* occasionally occurs in cattle, in which also the symptoms, progress, and proper treatment are similar to those detailed under that head in horse pathology.

698. *Inflammation of the stomach* sometimes occurs from poisonous matters and in such cases, when the nature of the poison is discovered, the treatment detailed under poison in horse pathology must be pursued. But there is a species of indigestion to which cattle are liable in the spring of the year, particularly of the young sprouts of wood to which some woods are more conducive than others. The symptoms are heat, thirst, loose stools, loosened urine, quick and hard pulse, with heat and redness in the mouth and nose, the belly is hard and painful and the stools when they appear are covered with glass. When the mouth and nose discharge a serous fluid the animal usually dies.

699. *Treatment.* Bleed at first, open the bowels by saline purgatives (683.) After this give large quantities of nitrated water and ginger also largely.

700. *The hoar or melen* in cattle is also an inflammatory affection of the paunch arising in paralysis and rupture of its substance. From the frequency of its occurrence it has become a subject of investigation with almost every rational grazier and a particular matter of enquiry with every agricultural body whence it is now very successfully treated by the usual attendants on cattle, when skilful, but when otherwise, it usually proves fatal. It is observed to be more frequent in warm countries than where the grass is wet. When either oxen, cows, or sheep meet with any food they are particularly fond of or of which they have been long deprived — as potatoes, turnips, the different grasses, particularly red clover, — they eat greedily, and forget to lie down to ruminate, by which means the first stomach or paunch, becomes so distended as to be incapable of expelling its contents. From this inflammation follows, and fermentation begins to take place. A large quantity of air is let loose, which still adds to the distension, till the stomach either bursts, or by its pressure on the diaphragm, the animal is suffocated. The situation of the heart is known by the urenae and general swelling of the abdomen, with the circumstances of the animal being found with such food, or the presumption that it has met with it.

701. *Treatment.* There are three modes of relieving the complaint, the first, which may be adverted to according to the degree of distension and length of time it has existed. These are internal medicines, the introduction of a proboscis of some kind into the paunch by the throat, and the puncturing it by the sides. Dr. Whyatt, of Edinburgh is said to have cured eighteen out of twenty hoar cows, by giving a pint of gin to each. Oil, by condensing the air has been successfully tried. Any other substance, also, that has a strong power of absorbing air may be advantageously given. Common salt and water made strongly saline, is a usual country remedy. New milk with a proportion of tar equal to one sixth of the milk, is highly spoken of. A strong solution of prepared ammoniac in water often brings off a great quantity of air and relieves the animal. Any of these internal remedies may be made use of when the hoar has recently taken place, and is not in a violent degree. But when otherwise, the introduction of an instrument is proper and is now very generally resorted to. The one principally in use is a species of proboscis invented by Dr. Monro, of Edinburgh. Another consisting of a cane of six feet in length, and of considerable diameter, having a bulbous knob of wood has been invented by Enger which is a more simple machine but hardly so efficacious. It is probable that, in case of emergency even the larger end of a common cart-whip, dexterously used might answer the end. But by far the best instrument for relieving hoar cattle as well as for clystering them, is Read's eviscerator, which is alike applicable to horses, cattle, and dogs. It consists of a syringe (fig. 870 a.) to which tubes of different kinds are applied, according to the purpose, and the kind of animal to be operated upon. There is a long flexible tube for giving an osseous to horses and cattle (a) and a smaller one for dogs. (b) To relieve barren bullocks effectually it is necessary not only to free the stomach from an accumulation of gas but from the fermenting pulsatious mixture which generates it, for this purpose a tube (c) is applied to the extremity of the syringe, and then passed into the animal's stomach through the mouth (d), and being put in action, the offending matter is discharged by a side opening. When the same operation is performed on sheep, a smaller tube (e) is made use of. The characteristic excellency of Read's instrument is, that there is no hurt to the quantity of fluid that may be injected or extracted. The same syringe is used for extracting poison from the stomach of man, for smoking insects, extinguishing fires, and syringing fruit trees. (Enger of Gard. &c. ed. 1816.) The introduction of any of these instruments may be effected by the help of an assistant, who should hold the horn of the animal by one hand, and the dividing cartilage of the nose with the other while the operator himself, taking the tongue in his left hand, employs his right in skilfully and carefully introducing the instrument; the assistant bringing the head and neck into such an attitude as to make the passage nearly straight, which will greatly facilitate the operation. But when no instruments can be procured, or as cases may occur when indeed it is not advisable to try them, as when the disease has existed a considerable time, or the animal has become outrageous, or the stomach so much distended with air that there is danger of immediate suffocation or bursting. In these instances the puncture of the maw must be instantly performed which is called *paracentesis*. This may be done with the greatest ease, midway between the ilium, or haunch-bone, and the last rib of the left side, in which the paunch inclines. A sharp penknife is frequently used, and persons in veterinary practice should always keep a long trocar which will be found much the most efficacious, and by far the most safe, as it prevents the air escaping certainly and quickly at the same time that it prevents its entrance into the cavity of the

distillation, which would occasion an equal distention. As soon as the air is perfectly removed, and the stomach resumes its office, the trochar may be removed; and, in whatever way it is done, the wound

870

should be carefully closed with sticking plaster or other adhesive-matter. It is necessary to observe, that this operation is so safe, that whenever a medical assistant cannot be obtained, no person should hesitate a moment about doing it himself. After relief has been afforded by means of either the probing or the puncturing, a stimulant drink may yet be very properly given, such as half a pint of common gin; or one ounce of spirit of hartshorn in a pint of ale, or two ounces of spirit of turpentine in ale, may any of them be used as an anasthetic stimulus. When also the end is again chewed, still some relaxation of the digestive organs may remain at first, therefore, feed sparingly and give, for a few mornings, a decoction. (825) No. 1.)

8254. *Inflammation of the bowels or red colic*, is by no means unknown in cattle pathology; the symptoms of which do not differ from those common to the horse, and the treatment also is in every respect the same. (8463.)

8255. *Inflammation of the liver or hot yellows* sometimes occurs, in which case, in addition to the symptoms detailed under hepatitis in the horse (8478.) there is, from the presence of cystic bile in the ox, a more determined yellowness of the eyelids, mouth and nostrils, the *stomach* must be similar. (8479.)

8256. *Inflammation of the kidneys called red water* by the cow-leeches, is not uncommon among cattle, and is, perhaps, dependent on the lobulated form of these parts in them. The animal, to the other symptoms of fever, adds stiffness behind, and often straddles, but always shrinks on being prodded across the loins, where frequently lacerated heat is felt; the urine is sometimes scanty and now and then increased in quantity, but it is always first red, then purple, and afterwards brown or black, when a fatal termination may be prognosticated. The treatment has been fully detailed under nephritis, in the horse pathology (8481), and it consists in plentiful bleedings, &c. carefully abstaining from the use of diuretics, as advised by ignorant cow-leeches.

8257. The black water is only the aggravated and latter stages of the above.

8258. *Inflammation of the bladder* also now and then occurs, and in no wise differs from the cystitis of the horse in consequences and treatment. (8483.)

8259. The colics of cattle arise from different causes they are subject to a *spasmodic colic* not unlike that of horses, and which is removed by the same means. (8474.) *Constipation* also brings on a colic in them, called *one bowel*, *farset bound*, &c. which often ends in the red colic, unless early removed; the treatment of this we have fully detailed. (8476.) Another colic is accompanied with relaxation of bowels.

8260. *Diarrhoea, scouring or scouring cow*, is common in cattle and is brought on by exposure to rain, improper change of food, over-driving, and other violence. It is essentially necessary that the animals be taken under cover kept warm and dry and have nutritious food allowed them. The medical treatment has been detailed. (8475.)

8261. *Dysentery, or bloody ray and sitting flux*, differs from simple scouring in a greater degree of fever attending it, and in its being an inflammation of a particular kind, and part of the intestines. It is frequently dependent on a vitiated putrid state of the bile, brought on by over-driving in hot weather, low damp pastures in autumn, &c. The discharge is characterised by its bad smell, and by the mucous stringy gushes in it, and also by its heat and smacking when voided. All which are very different from the mere discharge of the elements in a state of solution in diarrhoea, and which differences should be carefully marked, to distinguish the one from the other. Treat as under dysentery in the horse. (8470.)

8262. *Yellow* When active fever is not present, and yet cattle are very dull, with great yellowness of eyelids, nostrils, &c., it arises from some biliary obstruction, to which oxen and cows are more liable than horses, from their being furnished with a gall bladder; it is a more common complaint in some of the cold provinces on the Continent, where they are housed and stall-fed all the year round, than it is in England. The treatment is the same as detailed for chronic inflammation of the liver in horses, (8484.) adding in every instance to it a change of pasturage, and if convenient, into salt marshes, which will alone often effect a cure.

8263. *Loss of the cud*. This enters the list of most cow-leeches diseases, but is less a disease than a symptom of some other affection; indeed it is evident that any attack sufficient to destroy the appetite, will generally occasion the loss of the cud. It is possible, however, that an occasional local adhesion or paralysis of the stomach may occur particularly when it is distended with unhealthy substances, as weeds, crabs, the tops of some of the woody shrubs, &c. The treatment, in such cases, consists in stimulating

the stomach by tallow, or shins, pepper and gin mixed though these, as liquids, may not enter the stomach in common cases, yet in this disease or injured action of the rumen they will readily enter there.

6964. *Sluggish, slow, or turning* use sometimes the consequence of over-feeding, particularly when from low keeping cattle are suddenly moved to better pasturage. Treat with bleeding and purging.

6965. *Typhus, or locked jaw*, now and then attacks cattle, in which case it presents the same appearances and requires the same treatment as in horses (6432)

6966. *Cystic surgery* is in no respect different from that in practice among horses, the wounds are treated in the same manner. Gearing with the horse will sometimes penetrate the cavity of the belly and let out the intestines the treatment of which is the same as in the horse. (5477) Burns, bruises, &c. are also to be treated like those of horses.

6967. *Foul in the foot*. This occasionally comes on of itself, but is more often the effect of accidents cleanse it well, and keep it from dirt. — apply the foot paste. (5267)

6968. *Warts, or puckerings* are tumours on the back of cattle, occasioned by a dipterous insect which punctures their skin, and deposits its eggs in each puncture, these tumours are erroneously attributed to the fern owl or goat-sucker (*Copromyza europæa* L.) When the eggs are hatched, and the larvae or maggots are arrived at their full size, they make their way out, and leave a large hole in the hide, to prevent which the destruction of the eggs should be attempted by nipping the tumour or thrusting in a hot wire.

6969. *Cattle sickness* is not very varied, young cows of very full habits have sometimes a superabundant secretion of milk before calving which produces fever and heat sometimes, from cold taken the same will occur after calving also in either case, give mild dry food, or hay beside the fodder also with vinegar and water in some cases, warm fomentations do best. If the fever run high, treat as under fever in horse pathology.

6970. *The process of calving* is usually performed without difficulty sometimes, however, cross presentations take place, and sometimes a coarctation of parts prevents the natural passage of the calf. To act properly on these occasions, great patience is required, and much kindness many cows have been lost by brutal pulling we have seen all the men and boys of the farm mustered to pull at a rope affixed about a calf partly protruded which when it was thus brought away was forced to be killed, and the mother soon died also from the protrusion of parts th a brutal force brought with the calf. A steady moderate pull, during the throes of the animal will assist much having first directed the attention to the situation of the calf, that the presentation is such as not to obstruct its progress if it does, the calf must be forced back, and turned aright.

6971. *Phthorizing or retention of the after birth or burden*. — It sometimes happens that this is retained for which no better remedy has been hitherto discovered than warm clothing and drenching with ale, administered as a forcer.

6972. *The diseases of calves* are principally confined to a species of *contumelia* which now and then attacks them and which sometimes arises from worms, and at others from cold. When the first cause operates, it is then relieved by giving a mild elastic purge, or in default of that, a mild dose of oil of turpentine as half an ounce, night and morning. In the second, wrap up the animal warm and drench with ale and laudanum a draught. Calves are also very subject to diarrhoea or *scouring* which will readily yield to the usual medicines. (5552)

SECT II *The Buffalo*. — *Bos bubalus* L. *Bufflo* Fr *Buffalo*, Span *Buffloche*, Ger and *Byfle*, Ital

6973. *The buffalo* is found wild in India, America, and various parts of the globe, and is in some degree domesticated in many countries. He is gregarious, docile, alert, and of surprising strength his carcass affords excellent beef and the horns, which are jet black and of a solid consistence take a polish of wonderful beauty they can be converted into fabrics of use and ornament, such as mugs, tumblers, knife-handles, &c. In this way they sometimes apply them and when ornaments of silver or mother-of-pearl are employed, the contrast with the polished black of the horn is agreeably striking. The boss on the shoulders is, as well as the tongue, extremely rich and delicious and superior to the best English beef. It is usual to cure the tongues for sale. The buffalo far surpasses the ox in strength. Judging from the extraordinary size of his bones, and the depth and formation of his chest, some consider him twice as strong as the ox and, as an animal of labour he is generally preferred in Italy. In this country the ingenious physiologist, Hunter has caused buffaloes to be trained to work in a cart. At first they were restive, and would even lie down but afterwards they became steady and so tractable, that they were driven through the streets of London, in the loaded cart, as quietly and steadily as in Italy or India.

6974. *The buffalo is kept in several gentlemen's parks* as an object of luxury and has been trained and worked by Lords Sheffield Egremont, and some other amateur agriculturists. Many prefer his flesh, and some his milk, to that of the bull family.

6975. *The breeding, rearing, and general treatment of the buffalo* may be the same as those of the bull family.

## CHAP V

### *The Dairy and its Management.*

6976. *The manufacture of butter and cheese* is of necessity carried on where the milk or raw material is at hand. The subject therefore forms a part of farm management, more or less on every farm, and the principal one in dairy farms. In most of those countries where the profit of the cow arises chiefly from the subsequent manufacture of the milk, the whole care and management of the article rests with the housewife, so that the farmer has little else to do but to superintend the depasturing of his cattle, the

milking, churning, and in short the whole internal regulation of the dairy, together with the care of marketing the butter, where the same is made up wholly for home consumption, falling alone upon the wife. In this department of rural economy, so large a portion of skill, of frugality, cleanliness, industry and good management, is required in the wife, that without these the farmer may be materially injured. This observation will indeed hold good in many other parts of business which pass through the hands of the mistress in a farm-house but there is none wherein he may be so greatly assisted, or so materially injured, by the good conduct or want of care in his wife, as in the dairy. The dairy husbandry is more extensively and successfully pursued in England than in Scotland or in Ireland. "As to dairy husbandry on any thing like an improved plan," says Aiton, "it is still confined to a mere corner of Scotland." This corner is the district of Cunninghamham, in Ayrshire, of which he observes "The excellence of the improved breed of cows in Ayrshire, as well as the superior quality of Strathaven veal the Glasgow butter and milk, and Dunlop cheese to all others in Scotland, are things that cannot be disputed." (*Aiton's Dairy Husbandry* Pref. p. 18.) We shall in giving the dairy husbandry of England glance, at the same time, at the peculiarities of the Ayrshire dairy husbandry as given by the author last quoted.

6577. *The operations of the dairy* in all its branches are still conducted perhaps more empirically than those of any other department of husbandry though it would appear that science, chemistry in particular might be applied to direct the principles, and regulate the practice of the art, with facility and precision. We have heard it credited an eminent author observes, even by experienced dairymen that the quality of their cheeses is more uniformly in the same season and we think but able to assign a reason. Every one knows how different the cheese of Gloucester is from that of Cheshire, though both are made from fresh milk the produce of cows of the same breed, or rather in both countries of almost every breed, and fed on pastures that do not exhibit any remarkable difference in soil climate or herbage. Even in the same district some of what must appear the most important points are far from being settled in practice. Marshall in his *Rural Economy of Gloucestershire* has registered a number of observations on the heat of the dairy room, and of the milk when the rennet was applied in cheese making; on the time required for coagulation and the heat of the whey after which are curious, only because they prove that no uniform rule is observed in any of these particulars. The same discrepancy is observable in all the subsequent operation till the cheese is removed from the press and even afterwards in the drying room. One would think the process of salting the cheese the most simple of all; and yet it is sometimes, as in the west of Scotland mixed with the curd. In other instances poured into the milk, in a liquid state before being coagulated; and still more commonly, never applied at all till the cheese are formed in the press, and then only externally. In treating of the dairy we shall first offer a few remarks on the nature of milk and the properties of that of different animals and next consider the dairy house and its furniture milking, churning cheese-making, and the different kinds of cheese, butters, creams, and other products of the dairy.

#### SECT. I. *Chemical Principles of Milk, and the Properties of the Milk of different Animals.*

6578. *The milk* used by the human species is obtained from various animals, but chiefly the cow, ass, ewe, goat, mare, and camel that in most general use in British dairying is the milk of the cow which in modern times has received great improvement in quantity as well as quality by ameliorations in the form of milch cows, in their mode of nourishment, and in the management of the dairy. Whatever be the kind of animal from which milk is taken its external character is that of a white opaque fluid, having a sweetish taste, and a specific gravity somewhat greater than that of water. Newly taken from the animal, and allowed to remain at rest, it separates into two parts; a thick white fluid called cream, which collects on the surface in a thin stratum and a more dense watery body which remains below. The quantity and quality of cream, and the time it requires to separate from the milk, vary according to the nature of the milk and the temperature of the atmosphere. Milk which has stood some time after the separation of the cream, first becomes acidulent, and then coagulates. When the coagulum is pressed gently a serous fluid is forced out, and the remainder is the caseous part of milk or pure cheese.

6579. *Butter* or solidified cream, one of the most valuable products of milk, is obtained artificially by churning an operation analogous in its effects to shaking or beating, by which the cream separates from the caseous part and serum, in a more solid form than when left to separate spontaneously. It is afterwards rendered still more solid by beating with a wooden spind.

6580. *Cheese* is obtained by first coagulating the milk, either with, or deprived of its cream, and then expressing the serum or whey the consolidated curd so produced forms cheese. The milk may be coagulated in various ways but that effect is chiefly produced by the use of rennet, which is prepared by digesting the coat of young ruminating animals, especially that of the calf. The rennet is poured into the milk when newly brought from the cow or the milk is warmed to 90° or 100° for that purpose. The richness of cheese depends on the quantity of cream which the milk may have contained; its quality of keeping on the quantity of salt added and the degree of pressure used to exclude the whey.

6581. *Whey* expressed from coagulated milk, if boiled, and the whole curd precipitated, becomes transparent and colorless. By slow evaporation it deposits crystals of sugar with some muriate of potash muriate of soda, and phosphate of lime. The liquid which remains after the separation of the salts is converted by cooling into a gelatinous substance. If a whey be kept it becomes sour by the formation of an acid, which is called the lactic acid and it is to this that the spontaneous coagulation of milk, after it remains at rest, is owing. Milk whey, after it is sour is fermented, and it will yield a vinous intoxicating liquor. This is practised by the inhabitants of the most northerly islands of Europe, with buttermilk, and by the Tartars with the milk of the mare. Milk is likewise susceptible of the acetous fermentation.

6582. *The constituent parts of milk* are found to be oil, curd gelatine, sugar of milk, muriate of soda, muriate of potash phosphate of lime, and sulphur. These substances enter into the milk of all animals, but the proportions vary in different species. The various milks in use as food are thus distinguished.

6583. *Cow's milk* produces a copious, thick, and yellow cream, from which a compact consistent butter is formed; the curd is bulky and retains much serum, which has a greenish hue, a sweet taste, and contains sugar of milk and neutral salts. The milk of the buffalo is essentially the same as that of the cow.

6584. *Ass's milk* throws up a cream resembling that of woman's milk the butter made from it is white, soft, and dissolves to be melted. The curd is similar to that of the woman, but not unctuous the whey is colorless, and contains less salts, and more sugar, than that of the cow.

6585. *Mare's milk* throws up as much cream as that of the cow and of nearly the same colour the butter made from it is yellow and soft; the curd is fat and viscid the whey is colorless, and contains the smallest quantity of sugar of any milk and but a small portion of muriate and phosphate of lime.

6586. *Donkey's milk* produces abundance of cream, which is thicker and whiter than that from the cow;

the butter is white and soft, and equally copious, and as in the curd, which is of a firmer consistence than that of the cow and retains less whey.

6987 *Man's milk* produces a very fluid cream, similar in colour and consistence to good cow's milk before the cream appears on the surface. The butter rises from it has but little consistence, and is readily decomposed. The curd is similar to that obtained from woman's milk, and the whey has little colour and contains a large proportion of saccharine matter and of saline substances.

6988 *Camel's milk* throws up little cream, which is whitish and thin, affording soupy whitish butter the curd is small in quantity and contains but little whey which is coloured and somewhat saccharine.

6989 *Don's milk*. In China, especially about the city of Canton no other milk can be had but that of the don. It is rather sweeter than cow's milk but very similar in all other respects.

6990 *In the use of these milk* that of the camel is chiefly confined to Africa and Asia and that of the mare to Tartary and Siberia. In India the milk of the buffalo is preferred by the natives to that of the domestic cow. The milk of the goat is more generally used in Italy and Spain than in any other country in Europe. They are driven into Lagnhorn Florence Madrid, and other towns, in flocks early in the morning and milked in the streets. The goat will allow herself to be suckled by the young of various other animals, and a fawn which has lost its mother has been suckled by a goat, placed on a barrel to facilitate the operation. As the butter or goat's milk contains a larger proportion of gelatine and less oil than that of the cow, it is recommended by physicians as nearly equally light as cow's milk. It is the most prolific of all in curd, and forms excellent cheese but it is an error to suppose that the Parmesan (a skim milk cheese) is made from it. Ewe's milk is gradually wearing out of use, though it makes excellent cheese and some milking ewes as well as goats might be kept for that purpose, by those who have extensive upland grass-lands. The milk of the ass comes the nearest to that of the woman, and being the lightest of any is much recommended in pulmonary and hepatic affections. Soda water and warm cow's milk is taken as a substitute and found almost equally light. The milk is universal use, as an article of food in Britain, is that of the cow.

6991 *Instructions for ascertaining the value of milk*, relatively to butter and cheese will be described among the utensils of the dairy in the succeeding section.

## SECT. II. The Dairy House its Furniture and Utensils

6992 *The dairy house for general purposes* consists of at least three separate apartments, the milking room, the dairying or working room, and the cheese or store-room. The two former are generally separated by a passage or lobby; and the latter is very frequently a loft over the whole, entered by a stair from the lobby.

6993 *The properties requisite in a good milk house* are that it be cool in summer and moderately warm in winter so as to preserve a temperature nearly the same throughout the whole year or about 45 degrees, and that it be dry so as to admit of being kept clean and sweet at all times. For these reasons a northern exposure is the best, and this as much under the shade of trees or buildings as possible. If it can be so situated that the sun can have no influence either on the roof or walls so much the better.

6994 *A well constructed butter dairy* should consist of three apartments, a milking house, a churning house, with proper boiler as well as other conveniences for scalding and washing the implements, and a room for keeping them in, and for drying and airing them, when the weather will not permit of its being done without doors.

6995 *The cheese dairy* should likewise consist of three apartments, a milk house, a scalding and pressing house and a salting house. It is essential to the cheese dairy to have a command of heat during the cold season. When milk is exposed to a degree of cold below 50° at any time, from the moment it is drawn from the cow till the cheese is not only pressed, but to a great extent, dried, the cheese will not be good. "It is not enough that the milk be again heated, it must never be allowed to become too cold at any time, not even in the press, or if it is the quality of the cheese will be much injured." (*Adon's Dairy Husband* p. 82.) To these should be added a cheese room or loft, which may with great propriety be made above the dairy. This is however generally separate from the dairy. But a milk dairy requires only a good milk house, and a room for salting, cleaning, and airing the utensils. The use of the milk-house, according to *Adon* ought to be sufficient to contain one day's milk of all the cows belonging to it.

6996 *A dairy for the private use of any farmer or family* need not be large, and may very economically be formed in a thick walled dry cellar so situated as to have windows on two sides, the north and east in preference for ventilation and in order that these windows may the better exclude cold in winter, and heat in summer, they should be fitted with double sashes, and on the outside of the outer sash should be a fixed frame of close wire netting, or hair cloth to exclude flies and other insects.

6997 *Of dairies for dairy farmers* there are different sizes and shapes.

6998 *A dairy-house connected with a cow house*, and mill for preparing food for the cows, churning and washing the family linen, is thus arranged. (*Fig 871*.) The dairy (a, b, c, d) is at the north end, has

hollow walls, double doors, double sashed windows, and an ice-house under. The milk room (a) is surrounded by milk coolers, and has a butter slab and jet in the centre. The jet is supplied from a cistern over the standing house (f, g, h), to which the water is raised from a well by a forcing pump worked by the

the wheel. Besides supplying the jet, it furnishes, by cocks and pipes, water for the usual dairy purposes, the steaming or boiling of food for the cows, their drink and washing out the cow-house, the washing of the cheese-rooms (g) and store closet (d). The gin wheel (c) is separated from the milk-room by double doors, as is the latter from the cheese-rooms (g) and store closet (d). The gin wheel (c) is worked by one or two horses, or even oxen, according to the work to be done. The steaming and washing room (f g) is a large roomy apartment properly fitted up, and furnished with two boilers, a machine for steaming cattle food, another for washing linen by steam, one impelled by the gin wheel operating on an axle with levers or lifters (fig. 578), and a cylinder of open space, which turns round in a box of water for washing potatoes or other roots. The cow house (h A) is calculated for forty cows to be fed from a broad passage in the centre. At the south end is a large apartment (i) open to the roof for hay, straw, green herbage for milking, turnips, and other food, and under it is an armarium vaulted, and from which the liquid is drawn by a Buchanann pump (4464), outside of the building, and some yards distant.

7000. The dairy-house recommended by Dr. Anderson is surrounded by double walls, the inner of brick or stone, nine inches or a foot in thickness, and the outer about two feet distance, built of stone or turf, or a bank of earth faced with turf may be placed against the inner wall.

7001. The size of the dairy house should vary according to that of the number of cows. Marshall found in Gloucestershire one for forty cows to be twenty feet by sixteen and one for one hundred, thirty by forty. The North Wiltshire dairy-rooms have in general, he says, outer doors, frequently opening under a pent-house or open lean-to shed, which is a good convenience affording shade and shelter, and giving a degree of coolness to the dairy room. In one instance he observed two doors, a common close-boarded door on the inside, and an open-paled gate-like door on the outside, giving a free admission of air in close warm weather, and at the same time, being a guard against dogs and poultry. A convenience which he thinks would be an improvement to any dairy room is the summer season. The inside wall may be seven or eight feet high in the sides, on which may be placed the couples to support the roof, and the walls at the gables carried up to the height of the couples. Upon these should be laid a roof of reeds or thatch that should not be less than three feet in thickness, which should be produced downward till it covers the whole of the walls on each side to the ground, but here, if thatch or reeds be not in each plenty as could be wished, there is no occasion for laying it quite so thick. In the roof, exactly above the middle of the building, should be placed a wooden pipe of a sufficient length to rise a foot above the roof to serve occasionally as a ventilator. The top of this funnel should be covered to prevent rain from getting through it, and a valve fitted to it, that by means of a string could be opened or shut at pleasure. A window also should be made upon one side for giving light, to be closed by means of two glass frames, one on the outside, and the other on the inside. The use of this double sash, as well as the great thickness of the wall, and of the thatch upon the roof, are to render the temperature of this apartment as equal as possible at all seasons of the year by effectually cutting it off from having any direct communication with the external air.

7002. The dairy-house made use of by Wakefield of Liverpool contains three apartments; a milk-house, churning-room, and the room for the utensils. In the milk-house were the coolers, a slab for laying butter on after it is made up, cocks for drawing off the milk from the coolers, a large cock to throw water on the floor, which slopes a little from that part; cocks at the back part of the coolers, for letting in water a door, latticed and another door most commonly used but panelled. In the churning-room is a fire-place, a boiler, a large copper, also used when brewing. The room for drying or airing the utensils is also used occasionally as a laundry.

7003. A very good dairy for a private family may be made under the shade of two or three tall trees, in the following manner — Build the walls of bricks, and hollow in Silverlock's manner, by which every course of brick-work is laid on edge, and forms oblong cavities (fig. 573. e) the bricks of the one course being laid alternately lengthways (b) and crossways (c) and those of the next breaking joint with these, by the cross ones being placed on the middle of the long ones (d). The elevation of such a wall (e f g) should of course be founded on solid work, of breadth and thickness according to the height of the wall, and nature of the foundations. The plan of a dairy with such walls should contain the three usual apartments for milk, churning and utensils (h) and should have double doors and windows the latter guarded by wire. The elevation (f) may be of any style of simple architecture.

7004. As a complete dairy on a large scale we submit the following. The plan (fig. 574) is of an oblong form, and consists of the three usual principal apartments, enclosed by walls of four inches in thickness, and surrounded by a passage two feet wide to the north and three feet to the south, which is again surrounded by a nine-inch wall. The plan (fig. 574) is of an oblong form, and consists of the three usual principal apartments, enclosed by walls of four inches in thickness, and surrounded by a passage two feet wide to the north and three feet to the south, which is again surrounded by a nine-inch wall.

each wall. The passage communicates with the roof by covered openings, in the ridge of which and by the windows ventilation is completely effected. In detail, the plan exhibits two principal entrances porch (a) back entrance (b), copper for boiling water (c) churning-room (d), milk-room (e) utensils

and cheese-press (f) boiler for heating milk (g), store closet or butter room (h), cheese-room (i), passage surrounding the whole (k), water closet (l) and windows to cheese-room (m).

7004. A section (fig. 875.) taken across the milk-room (fig. 874 see) exhibits the ventilating funnel in the roof (a), projecting eaves (b, c), cheese-room (d), passage on the north side (e) (edged part of the roof for ventilation (f g) fountain in the centre of the dairy (h), and south passage (i).

7005. The elevation (fig. 876.) presents a simple shed roof, varied, however by projections and recesses. It presents no windows or doors to the south, and therefore that side, if other circumstances permit, may be covered with vines or other fruit-trees, or with ornamental creepers.

7006. The fixtures of the dairy are, in the scalding-room, a copper boiler fired over a

fire-place, for boiling water to wash and scald the utensils; next, some benches and shelves in this room and the cheese-room; and a bench or table not more than two feet wide surrounding the milk-room. It is very desirable, also, that there should be a jet, or fountain, or pump, or spring, in the centre of the milk-room, in order to cool down the air in summer and to supply clear water at a moderate temperature at all times.

7007. The utensils of the dairy are, pails for milking; into moves of hair-cloth or silver wire-cloth for passing the milk through to free it from hairs and other impurities; milk dishes, or coolers, for holding the milk till it throws up its cream; a cream-knife of ivory for separating, and skimming dishes of willow or ivory for removing the cream; bowls and barrels for holding it, or other preparations of milk-churns, butter-makers, butter-prints; one or more tubs for hot or cold water in which to immerse vessels that require extraordinary purification; and a portable rack for drying dishes in the open air. All these utensils are requisite where butter only is to be produced.

7008. The utensils requisite of cheese as to be made are the cheese-tub in which the curd is broken, and prepared for being made into cheese; the cheese-knife generally with a spatula of wood, but sometimes of iron used for the purpose of cutting or breaking down the curd while in the cheese-tub. The cheese-board is a piece of thin gauze like linen cloth in which the cheese is placed in the press; the cheese-board is circular and on it the cheeses are placed on the shelves of the cheese-room; their diameter must be somewhat less than that of the interior or hoop part of the vat. The vat is a strong kind of wooden hoop with a bottom, which as well as the sides, is perforated with holes to allow the whey to escape while the cheese is pressing; the size of vats must depend on that of the cheese and the number required as of most of the other implements on the extent of the dairy.

The cheese-press (fig. 877) is a power generally obtained by a screw though sometimes by a dead weight, and is used for forcing the whey from the curd while in the vat. The cheese-logs are a wooden frame occasionally laid on the cheese-tub, when the vat is set on it in order to drain the whey from the curd. To these implements some add a lactometer one kind of which (fig. 878.) is a glass tube a foot long with a funnel at top. The upper two inches of the tube are marked in small divisions, and when the instrument is filled to the height of one foot with milk, the depth of cream it yields is noted by the gradations on the upper part. Another lactometer for ascertaining the richness of milk from its specific gravity by its degree of warmth taken by a thermometer on comparing its specific gravity with its warmth was invented by Duca, of Liver pool, but never came into use. Another invention for the same purpose was made by Mrs. Lovi, of Ed burgh, in 1816. It consisted of saccharine beads, by which the specific gravity of the milk is tried first when new-milked, and next when the cream is removed. When milk is tried as soon as it cools say to 60°, and again, after it has been thoroughly skimmed, it will be found that the skimmed milk is of considerably greater gravity, and as this increase depends upon the separation of the lighter cream, the amount of the increase or the difference between the specific gravity of the fresh and skimmed milk, will bear proportion to, and may be employed as a measure of the relative quantities of the oily matter or butter contained in different milks. The specific gravity of skimmed milk depends both on the quantity of the saccharo-saline matters, and of the curd. To estimate the relative quantities of curd, and by that determine the value of milk for the purpose of making cheese, it is only requisite to weigh the skim-milk, and ascertain the specific gravity of the whey. The

they will, of course, be found of lower specific gravity than the skimmed milk, and the number of degrees of difference affords a measure of the relative quantities of the curd. According to this hypothesis, the centrifugal bowl may be employed to ascertain the quality of milk, relatively both as to the manufacture of butter and cheese. (*Notes of the High School, v. part I.*)

703. As milk coolers and cheese presses there is considerable variation of form. Milk coolers are generally made of earthenware or wood; but of late years they have been formed of lead, earthenware, and cast-iron. Their general form is round, and diameter from one to two feet, but in extensive dairies they are often made several feet or yards in length, and from two to three feet wide, with hems at one or both corners to admit the escape of the milk after the cream is removed. The safest dish is wood, though it requires most labour to keep it sweet; next is earthenware or China, though on the leaden glass of the former the acid of the milk is apt to operate. Leadon dishes or troughs, though very popular in Cheshire, are the most dangerous, and the objection to stoneware is the porosity of this glass, which are always unglazed, imperfect, and liable to be operated on by the lactic acid. The so-called and named cast-iron dishes of Baird's invention (in 1806) and which are now becoming universal in Scotland (*Notes of Dairy H. p. 81*) are perhaps the best for such as do not choose to go to the expense of China dishes. They are durable from the nature of the material, not liable to be broken by falls by being knocked, easily kept clean from being turned smooth, and also very economical, and said to throw up more cream from a given quantity of milk than any other.

7010. Besides the common plunge and barrel churns there are a number of improved sorts. One of the best for using on a small scale is the patent box churn (fig. 878) and on a large scale, the plunge churn, worked by levers put in motion either by a man or horse. The Derbyshire churn (fig. 880), which works on the principle of the barrel churn, is an excellent implement on a large scale. The bottom is a segment of a circle, and the advantage of the plan is, that when the butter is made, the lid (a) being

removed, the beaters (b) may be taken out at pleasure by withdrawing the spindle (c) to admit the removal of the butter, or the cleaning and scalding of the churn.

7011. The Lancashire plunge churn (fig. 881) is a simple and effective implement, worked by the

operator standing on the levers (a, b) throwing his whole weight alternately on each, so as by means of the line (c, d) connected with the churn staff to raise it and turn it round and lower it and turn it round alternately.

7012. The most exquisite cleanliness in the dairy is an essential requisite, as to the walls, floor, shelves, benches, and in the different utensils.

7013. The milk coolers and all the dishes in which milk is put, as well as the churn must be scalded, scrubbed, rinsed, and dried every time they are used. Scalding is less frequently requisite in the cheese utensils but they also must be almost daily washed in hot water, dried, and aired. When any vessel becomes tainted with the acidity of milk, it operates like leaven on what is put into it. If this taint cannot be removed by ordinary scalding, it may be boiled or immersed in water impregnated with alkali, but afterwards it must be well boiled, or a day or two immersed in pure water.

### SECT. III. Milking and the general Management of Milk.

7014. The times of milking vary greatly in different districts. In most places cows are milked twice in twenty four hours throughout the year, but in the best managed dairies where they are abundantly fed, they are milked at morning, noon, and the approach of night the additional quantity thus obtained is very considerable, but according to the experiments of Parmenter it must be inferior in quality for he found twelve hours requisite for the due preparation of the milk in the cow. Where quantity of milk or cheese is an object, three times milking must be decidedly preferable, but it is certain that in the best butter districts of England the cows are only drawn twice a day between five and six o'clock morning and evening. Whatever may be the times of milking it is essential that the milk be drawn off clear for if the milk which the cow can be made to yield at the time be not completely taken away, the quantity left will be reabsorbed into the system, and no more will be generated than is necessary to supply the quantity actually drawn off.

7015. The operation of milking is performed by men in many districts, but taking Britain generally it is more commonly the work of women. The milker, whether a man or woman, ought to be mild in manners and good tempered. If the operation be performed harshly it becomes painful to the cow who in this

more often brings into action her faculty of rejecting her milk at pleasure; but if gently persuaded, it seems rather to give pleasure, as is testified on a frequent occasion in *Thiolsdale*, and *Dehnbach*, where the cows come to be milked at the call of the milkers. Many instances have occurred, Dr. Anderson observes, in which cows would not let down a single drop of milk to one dairy-maid, whilst let it flow in abundance whenever another approached them; exhibiting unequalled marks of sensibility in the one case, and of sullen obstinacy in the other. For the same reason, when cows are sickish they should be treated with the most soothing gentleness, and never with harshness or severity; and, when their udder is hard and painful, it should be tenderly fomented with lukewarm water, and sucked gently by which simple expedient the cow will be brought into good temper and will yield her milk without restraint. Lastly as it sometimes happens that the teats of cows become scorched or wounded, so as to produce stiol or corrupted milk, whenever this is the case, such milk ought on no account to be mixed with the sweet milk, but should be given to the pigs, without being carried into the milk-house; last, by continuing there, it should scent the atmosphere, and consequently prove injurious to the rest of the milk.

7016. To promote cleanliness in regard to milking cows are in some places carried, combed, brushed, and clothed like horses; before milking their udders and teats are washed and dried, and their tails trimmed up. It would be well if a part of the refinement were adopted in all dairies; that of using the comb and brush, and washing the udder is indispensable in every establishment where clean milk is an object. According to *McWharty* scurfs, ticks, shuts, and daubles are unfit to be dairy-women, and no milker should ever be suffered to enter the dairy in a dirty apron covered with hairs from the cow house.

7017 The following aphorisms respecting the management of milk in the dairy are from the "Recreations" of Dr. Anderson, one of the most scientific writers on this subject.

1. Of the milk drawn from any cow at one time, that part which comes off at the first is always thinnest, and of a much worse quality than the residue obtained, and the richness continues to increase progressively to the very last drop that can be obtained from the udder.

2. If milk be put into a dish and allowed to stand till it throws up cream, the portion of cream rising first to the surface is richer in quality and greater in quantity, than that which rises in a second equal space of time and the cream, which rises in the second interval of time, is greater in quantity and richer in quality than that which rises in a third equal space of time that of the third is greater than that of the fourth and so of the rest the cream thus rising progressively to decrease in quantity and in decline in quality so long as any rises to the surface.

3. Thick milk always throws up a much smaller proportion of the cream which it actually contains than milk that is thinner, but the cream is of a richer quality and if water be added to that thick milk, it will afford a considerably greater quantity of cream, and consequently more butter than it would have done if allowed to remain pure, but its quality is, at the same time, greatly debased.

4. Milk, which is put into a bucket or other proper vessel and carried in it to a considerable distance, so as to be much agitated, and in part cooled before it be put into the milk-pans to settle for cream, never throws up so much, or so rich cream, as if the same milk had been put into the milk-pans directly after it was milked.

7018. From these fundamental facts, the reflecting dairyist will derive many important practical rules. Some of these we shall enumerate, and leave the rest to be discovered. Cows should be milked as near the dairy as possible, in order to prevent the necessity of carrying and cooling the milk before it is put into the creaming tubs. Every cow's milk should be kept separate till the peculiar properties of each is so well known as to admit of their being classed, when those that are most nearly allied may be mixed together. When it is intended to make butter of a very fine quality, reject entirely the milk of all those cows which yield cream of a bad quality, and also keep the milk that is first drawn from the cow at each milking entirely separate from that which is last obtained, as the quality of the butter must otherwise be greatly debased without materially augmenting its quantity. For the same purpose, take only the cream that is first separated from the first drawn milk. Butter of the very best quality can only be economically made in those dairies where cheese is also made, because in them the best part of each cow's milk can be set apart for churning up cream the best part of this cream can be taken in order to be made into butter and the remainder or all the rest of the milk and cream of the dairy can be turned into cheese. The spontaneous separation of cream, and the production of butter, are never effected but in consequence of the production of acid in the milk. Hence it is that where the whole milk is set apart for the separation of cream and the whole of the cream is separated, the milk must necessarily have turned sour before it is made into cheese and no very excellent cheese can be made from milk which has once attained that state.

#### SECT. IV. Making and Curing of Butter.

7019 The milk from which butter is to be made may either be put at once into the churn, and left there till it send up the cream or it may be made to cream in milk dishes, and the cream alone churned.

7020. The last is generally considered the best mode, and in carrying it into effect, the milk being drawn from the cow is to be strained into the creaming tubs, which should never be more than three inches deep, and of about a gallon and a half or two gallons in capacity. In general the best cream will be fit for removal in seven or eight hours, though for ordinary good butter it may stand twelve hours but where the very best butter is wished, and such arrangements are formed as admit of converting the milk to cheese or some other use while it is sweet, it may be separated after standing only two or three or four hours. In performing the operation first pass the cream knife round the edges of the vessel, to separate the adhering stratum of cream, and then draw it to one side, lift it off with the skimming dish, and put it in the cream bowl to be carried to the cream barrel.

7021. Cream may be kept from three to seven days before it is churned. Where quantity more than quality is desired, the whole of the milk is churned without separating any cream the milk is kept in the churn or in large barrels for two or three days, till it begins to get sour. The operation of churning, where the cream and milk are both so spoiled, is necessarily tedious and laborious but a great weight of butter is undoubtedly obtained, the quality and flavour of which will depend a good deal on the peculiar properties of the milk. The milk of Galloways, Ayrshires, and Alderneys, so treated makes excellent butter.

7022. In the process of churning great dexterity is required a regular stroke in plunge or pump churns, and a regular motion in those of the barrel or turning kind, must, if possible, never be deviated from. A few heavy vigorous strokes or turns has been known to spoil what would otherwise have been excellent butter. *Tremblay* (*Essays on the Dairy*) recommends the selection of a churner of a cool phlegmatic temper, of a steady disposition and character; and advises never to allow any individuals, especially the young, to touch the churn without the greatest caution and circumspection. To those who have been accustomed to see cream churned without being properly prepared, changing very perhaps, appear to be severe labour for one person in a large dairy but nothing is more easy than the process of making butter, where the cream has been duly separated.

7023. The best time for making butter, during summer is early in the morning, before the sun begins to make power; and if a pump churn be used it may be plunged a foot deep twice a tub of cold water, these

highland country during the whole time of shepherding; which will very much harden the butter. Flavour arising from the quality of decomposition, which, if it be properly managed, will generally prevail for a dairy, is not very easily, if ever, to be removed to secure near the fire, should any circumstances, however, require this, care should be taken not to stir so near the fire as to heat the wood; as it would impart a strong rancid taste to the butter. As soon as the butter is made, it must be separated from the milk, and be put into a clean dish the inside of which, if of wood, should previously be well rubbed with common salt, to prevent the butter from adhering to it. The butter should then be pressed and washed with a flat wooden knife or skimming-dish, having a short handle, so as to press out all the milk that may be lodged in the cavities of the mass. A considerable degree of dexterity, as well as of strength, is requisite in this manipulation. For, if the milk be not entirely removed, the butter will infallibly spoil in a short time, and if it be much washed, the butter will become tough and glaucous which greatly debases its quality. In some places it is the practice to beat up the butter with two flat pieces of beech, which may perhaps, answer very well. In this operation, some persons pour cold water upon the butter for the purpose of washing it: this practice, however, is not only useless for the butter can be perfectly cleared of the milk without it, but it is also pernicious, and debases the quality of the butter in an astonishing degree. Nothing is so detrimental in a dairy as water improperly used, which, if mixed in any way either with milk or butter, tends greatly to debase the quality of the latter.

7084. The best process now for clearing butter has been very satisfactorily determined by a number of experiments, sanctioned by the *Highland Society of Scotland*, and published in their *Transactions*. From these experiments it is concluded, that the most proper temperature at which to commence the operation of clearing butter is from  $40^{\circ}$  to  $50^{\circ}$ , and that at no time in the operation ought it to exceed  $65^{\circ}$ , while, on the contrary, if at any time the cream should be under  $40^{\circ}$  in temperature, the labour will be much increased, without any proportionable advantage being obtained, and a temperature of a higher rate than  $65^{\circ}$  will be injurious, as well to the quality as the quantity of the butter (*Highl. Soc. Trans. vol. vi. p. 182.*)

#### 7025 The making up of butter is the next process.

7025. *Butter being sent to table or market*, sweet or fresh butter is made up into various forms: sometimes into rolls or cylinders, six or eight inches long and from half an inch to two inches in diameter; at other times into small round figures, or casts, with impressions in relief from butter moulds. When the butter is too soft for the last purpose it may be put into small wooden vessels, which may be allowed to swim in a tub or cistern of cold water, or they may be set in an ice house for an hour or two, or the water in which the small vessels float may be iced. At all events, whatever mode is adopted, no water ought to be allowed to touch the butter. When formed into the desired shape, it may be placed in dishes, and set in the margin of the central stream of water till wanted.

7027. In salting or curing butter the use of wooden vessels is preferable and these vessels should be made from timber which has been previously boiled for four hours, to free it from the pyrogenous acid or they should be formed from the lime tree, which is confidently asserted (*Highl. Soc. Trans. vol. vii. p. 350*) to be without this acid. Whatever description of casks are used, they should previously be rendered as clean and sweet as possible, well rubbed with salt, and the cavity between the bottom and sides filled in with melted butter.

7028. An excellent composition for preserving butter may be made by reducing into a fine powder, and carefully mixing together, sugar and nitre, of each one part, and two parts of the best common salt. More to each pound weight of salt adds four ounces of raw sugar. Of this composition one ounce should be thoroughly mixed with every sixteen ounces of butter as soon as the latter has been freed from the milk, and the butter must be immediately put it to the firkin being pressed so close as to leave no air holes, or any kind of cavity, within it. The surface must be smoothed, and, if a day or two be expected to elapse before more can be added, the vessel must be closely covered up with a piece of clean linen, upon which should be laid a piece of wetted parchment, or (if this be not procurable) with a piece of fine linen dipped in melted butter that is exactly fitted to the edges of the vessel all round, so as to exclude the air as much as possible. When more butter is to be added, these coverings are to be removed. The butter is to be applied close upon the former layer, pressing it down, and smoothing it as before, till the vessel be full. The two covers are then to be spread over it with the greatest care, and a little melted butter is to be poured all round the edges, so as to fill up every part, and effectually to exclude the air. A little salt may then be strewed over the whole, and the cover be firmly fixed down. Butter thus cured does not taste well till it has stood at least a fortnight after it has been salted, but after that period it acquires a rich mellowy taste and will continue perfectly sweet in this climate for many years. As, however, its quality is liable to be impaired by being improperly treated while it is using, it will be necessary when the firkin is opened, first to pare off a small portion of the whole surface, especially near the edges, in case the air should, by any accident, not have been entirely excluded. If it is to be quickly consumed it may be taken up as it is wanted, without any other precaution than that of keeping it carefully covered up, but, on the contrary, if it is to be used very slowly, and if the person employed to take it up be not very careful in doing it up each time with the covers, the part which is thus exposed to the air will be liable to contract a small degree of rancidity. To prevent the occurrence of this inconvenience, when the vessel is opened, a strong brine of common salt (strong enough to float an egg) should be poured, when sold, upon the surface of the butter, and although the quality of the latter will be slightly injured by the action of the water upon it, yet that is a much less evil than the slightest rancidity would occasion.

7029. *Butter made.* The following is the plan adopted by Murr — 4 Cut the wood into deals of the lengths wanted, have a boiler of a square form, the length of the wood full of water, put in the wood with a weight or pressure, to keep it immersed in the water, and have a wooden cover on the boiler as it must be done by steam-evaporation. When thus boiled for four hours, the whole of the pyrogenous acid will be extracted. The wood is then dried for use. It becomes closer and more condensed, from the fibres being contracted. By this method, while the wood continues hot, it can be easily brought to any shape, and used for various purposes, and this is the only mode by which barrels for salted butter should be made. (*Highl. Soc. Trans. vol. vii. p. 356.*)

7030. *When butter is to be exposed to the heat of a warm climate*, it should be purified by melting before it is salted and packed up. For this purpose, let it be put into a proper vessel, and thus be immersed into another containing water. Let the water be heated till the butter be thoroughly melted, let it continue in this state for some time, when the impure parts will subside, leaving at the top a perfectly pure transparent oil. This, when it cools, will become opaque and assume a colour nearly resembling that of the original butter, being only somewhat paler and of a firmer consistence. When this refined butter is become a little cold, but while it is still somewhat soft, the pure part must be separated from the dregs, and be salted and packed up in the same manner as other butter, it will continue sweet much longer in hot climates, as it retains the salt better than in its original state. It may also be preserved sweet, without salt, by adding to it a certain portion of fine honey, perhaps one ounce to a pound of butter, and mixing them together thoroughly, so that they may be perfectly incorporated. A mixture of this sort has a most pleasant taste, and will keep for years without becoming rancid: there is no doubt, therefore, but that butter might thus be preserved in long voyages without spoiling.

7037. *An indigenous butter is mostly pale or white, and, at the same time, of a poorer quality than that made during the summer months. The idea of excelling has been associated with the yellow colour; hence, various articles have been employed in order to impart this colour. These most generally used, and certainly the most wholesome, are the juice of the butter, and of the flowers of five margined, carefully expressed, and strained through a linen cloth. A small quantity of this juice (and the requisite proportion is soon ascertained by experience) is diluted with a little cream, and this mixture is added to the rest of the cream when put into the churn. So small a quantity of the coloring matter united with the butter that it never imparts to it any particular taste.*

7038. *The butter most esteemed in London is that of Hypping and Cambridgeshire, the cows which produce the former feed during summer in the stubble pastures of Hypping down, and the leaves of the trees and numerous wild plants which sheep abroad are supposed to improve the flavour of the butter. It is brought to market in rolls from one to two feet long, weighing ten pounds each. The Cambridgeshire butter is produced from the milk of cows that feed on part of the year on chalky uplands, and the other in rich meadows or fens. It is made up into long rolls like the Hypping butter, and generally sold unadorned, when brought to market. By working at hand working the milk out of it, the London cheesemongers obtain a roll of a high price for fresh butter.*

7039. *The Hypping and Cambridgeshire butter is often sold for that of Cambridgeshire, to which it is little inferior. The butter of Gloucestershire is thought to equal that of Hypping. It is brought*

*to market in dishes, containing half a pound each, out of which it is taken, washed, and put into different forms by the buttermen of Bath and Bristol. The butter of Gloucestershire and of Oxfordshire is very good. It is made up in half-pound rolls or pieces, packed up in square baskets, and sent to the London market by sea, and*

7040. *In packing fresh butter or butter salted only for immediate use, the leaves of cabbage, white beet, or of the garden cress (*Atriplex hortensis*) are to be preferred. The bottom of the basket should be bedded with a thick cloth, folded two or three times, then a thin gauze, dipped in cold water, spread over it, on which the prints or rolls of butter are to be placed, each with one or more leaves beneath and smaller ones in it. The lowermost layer being adjusted, fold half of the gauze cloth over it, put in another layer in the same way, and thus cover with the remainder of the gauze. The butter should be put into the basket, as well as taken from thence, without being touched.*

7041. *Whey butter as its name implies, is butter made from the whey which is taken from the curd after the milk is coagulated for the manufacture of cheese. It is chiefly made in those counties where cheese is manufactured, and where it forms no inconsiderable part of the profits of the dairy. In the county of Derby more butter is said to be made from whey than from the cream of milk, or from milk churned altogether.*

7042. *Whey is divided into two sorts, green and white, the former escaping readily from the curd, while the latter is freed from it by means of pressure. "There are different methods of extracting the whey in some dairies the whole whey when taken from the cheese-tub, is put into pails or other vessels, where it remains for about twenty-four hours. When it is strained and the whey is applied to the use of calves and pigs, which are said to thrive as well on it, after the cream has been taken from it, as before. The cream, when skimmed off the whey, is put into a brass pan and boiled, and afterwards set in pans or jars where it remains till a sufficient quantity for a churning be procured, which, in large dairies, happens generally once, but sometimes twice, in the week." In Ayrshire whey is given to horses.*

7043. *Butter forming an important article of commerce as well as food, the legislature has passed various statutes respecting its package, weight, and sale. The principal of these are the 56th and 58th of Geo. III.*

## SECT. V. Process of Cheese-making.

7044. *The production of cheese includes the making of rennet, the selection of a colouring matter the setting of the curd, and the management of the cheese in the press.*

7045. *The milk fresh drawn from the cow is to be immediately strained into the ditches or shallow troughs, if these are used in order to promote cooling as the surest guard against fermentation. The same object may be attained by repeatedly drawing off the milk from the cooler, and pouring it back again.*

7046. *To understand what rennet is, and its uses, it is necessary to premise that milk is no sooner taken into the stomach, than it becomes curdled by the operation of the gastric juice, as every one who has seen much of infant children must have observed. What is called rennet is nothing more than the stomach of an animal in which the gastric juices are preserved by means of salt.*

7047. *The application of any kind of acid will cause milk to coagulate, as well as the infusion of several plants, as ladies' bedstraw (*Galium verum*) butter wort (*Fragula vulgaris*), and others. With the former plant the Jews coagulate the milk for all their cheese. The Moslems prohibit them to mingle meat with milk, and rennet they consider as meat.*

7048. *The maw or stomach of ruminating animals which admit of obtaining the gastric juice in a less mixed state than those of others, and chiefly of a young calf that has been killed before the digestion is perfected, is almost universally preferred as rennet. This bag or maw is cleaned and salted in different ways in different districts but the following method, described by Marshall in his *Rural Economy of Norfolk*, is considered as one of the best. "Take a calf's bag, maw or stomach, and having taken out the curd contained therein, wash it clean, and salt it thoroughly inside and out, leaving a white coat of salt over every part of it. Put it into an earthen jar, or other vessel, and let it stand three or four days, in which time it will have formed the salt and its own natural juice into a pickle. Take it out of the jar and hang it up for two or three days, to let the pickle drain from it. Re-salt it, press it again in a few cover it tight down with a paper plastered with a large pen, and in this state let it remain till wanted for use. In this state it ought to be kept twelve months. It may, however, as case of necessity, be used a few days after it has received a second salting, but it will not be so strong as if kept a longer time."*

7049. *In order to prepare the rennet for use Marshall gives the following directions.—"Take a handful of the leaves of sweet-brian, the same quantity of the leaves of the dog-rose, and the like quantity of bramble leaves. Toss them in a gallon of water with three or four handfuls of salt, about a quarter of an hour. Strain off the liquor, and, having let it stand till perfectly cool, put it into an earthen vessel, and add to it the maw prepared as above. To this is added a good pound measure, stick round with about a quarter of an ounce of cloves, which give the rennet an agreeable flavour."*

7050. *The strength of the rennet thus prepared will increase in proportion to the length of time during which the bag remains in the liquor. The quantity to be used for the purpose of coagulating milk see, therefore, be ascertained only by daily use and observation. In general, however, it may be stated, that the rennet, that somewhat less than half a pint of wine measure will suffice for fifty gallons of milk, for which quantity in Gloucestershire, the practice is to employ about one third of a peck. Throughout the whole process of preparing and preserving*

lines and sweaters; for if it be kept too long, so as to become foul or tainted, the cheese will invariably become affected by it, and will prove unfit for use.

7046. In Holland a small quantity of the mastic acid is used instead of rennet, and it is the use of this article which gives to the Dutch cheese that pungent relish which induces so many persons to prefer it.

7047. *Colouring matter.* As cheese in its native state, that is, such as is well manufactured, being put together in proper time, the milk being of a proper degree of warmth, and in all other respects properly pressed, salted, and dried, is uniformly of a bright yellow cast, the idea of excellence is generally attached to cheese of such a colour. Hence it has become necessary for the dairyman, who would dispose of his cheese to advantage, to impart a light yellow orange colour to it by artificial means.

7048. Turmeric, mangelwurz, American roots, and other vegetables, were formerly employed for this purpose, but these have long since been rejected for the *Annatto* roots, which is unquestionably the best ingredient of the kind that can be used for the colouring of cheese. It is a preparation of the roots or annatto tree (*Bixa Orellana* Lin. *Ag.* 1081), which is a native of America. The red pulp, that covers the seeds of this tree, is suspended in hot water, and allowed to subside, and when dry is formed into cakes or balls, which are further not made until they become completely dry and firm. One ounce of this substance, when genuine, will be sufficient to colour an hundred weight of cheese, and this is the common allowance in the county of Gloucester. In colouring, the weight of a guinea and a half is considered to be sufficient for a cheese of sixty pounds weight. The usual mode of applying the annatto is to dip a piece, of the requisite size and weight, in a bowl of milk, and rub it on a smooth stone until the milk assume a deep red colour. This infusion is to be added to the milk, of which cheese is intended to be made, in such a quantity as will impart to the whole a bright orange colour which will become the deeper in proportion to the age of the cheese. The mixing of the annatto in no respect affects either its taste or smell.

7049. In the county of Cheshire, however, a somewhat different practice obtains. There, when the colouring matter is wanted, it is usual to tie up as much of the substance as may be deemed sufficient in a linen rag, putting it into half a pint of warm water, to let it stand over night. In the morning, immediately before the milk is coagulated, the whole of this infusion is mixed with it in the cheese-tub, and the rag is dipped in the milk, and rubbed on the palm of the hand until all the colouring matter is completely extracted. A more simple method is directed by Parkinson — "Take, say he, a piece about the size of a hand nut, put it into a pint of milk the night before you intend to make cheese, and it will dissolve. Add it to the milk at the time the rennet is put in. The quantity will suffice to colour a cheese of twenty pounds weight." (*Parkinson on Live Stock*, vol. 1 p. 62.)

7050. *Setting the curd.* The proper season for making cheese is from the beginning of May till the close of September, or in favourable seasons till the middle of October. Very good cheese, however, may be made in winter, provided the cows be well fed. A certain elevation of temperature is requisite to the coagulation of milk, and it may naturally be supposed to be nearly that of the stomachs of milk-taking animals. Marshall is of opinion that from 85 to 90 degrees of heat, and two hours of time, are the fittest for coagulation.

7051. Climate, season, weather, and pasture may require that three hours should sometimes be violated. Milk produced from poor days will require to be coagulated at a higher temperature than that which is procured from rich pastures. In some dairies the milk is heated to the proper temperature, but the most approved practice is to mix boiling water in such a proportion as shall render the milk of a proper degree of heat to receive the rennet: thus the thermometer should be used to determine. In hot weather the milk in the cows' udders is liable to become very much agitated by their running about, or being driven to too great a distance, so that if rennet be put to it in this state, the curd, instead of coming in one or two hours, will require three, four, or five hours, and will be so spongy tough, and in every respect so imperfect, as to be scarcely capable of being confined in the press or vat, and when released from the press, it will heave or split, and be good for little. Whenever therefore cows are discovered to be in this state, which perhaps can scarcely be avoided during very hot weather, where cows are pastured abroad, in unsettled grounds, or where water is not within their reach, it will be advisable to add some cold fresh spring water to the milk as soon as it is brought into the dairy. The quantity to be mixed, in order to impart the proper degree of heat, can in this case only be regulated by experience and the use of the thermometer. The effect of the water thus added will, in both cases, be to make the rennet take effect much sooner, and consequently to accelerate the coagulation of the milk.

7052. The proportion of rennet and time requisite for coagulation have been already mentioned (7046, 7050.) too much rennet ought not to be put in, otherwise the cheese will be ready to heave, as well as become rank and strong. The same effect will also be produced if the rennet be made with bad or foul materials, or if it be too strong to operate in the given time (two hours). During the process, the milk ought to be covered so as not to lose more than five or seven degrees of its original heat. One or two handfuls of salt added previously to mixing the rennet will promote coagulation. Some put in a bowl, which is an absurd ancient custom, and injurious rather than useful.

7053. When the coagulation has taken place, the curd is broken or cut with a cheese-knife which causes the whey to run through the mass, and the curd sinks with more ease. After a short time the cutting is repeated, still more freely than before, and is continued until the curd is reduced to small uniform particles. This operation will require about three quarters of an hour. The cheese tub is again covered with a cloth, and is allowed to remain for the same time. When the curd has sunk to the bottom of the vessel, the whey is taken off by the hand, or by means of a skimming-dish, another quarter of an hour should now be allowed for the curd to settle, drain, and become solid, before it is broken into the vat, as it prevents the fat from being squeezed out through the fingers, and of course contributes to improve the quality of the cheese. Sometimes, in addition to the skimming-dish, a semicircular board and weight, adapted to the size of the tub, are employed. The curd is again cut as before, in order to promote the free separation of the whey, and pressure is again applied till it be wholly drawn off. Great attention is requisite in conducting this part of the business, and if any particles of sharp curd should be seen floating in the whey it ought to be carefully fished off with the whey, as it will not incorporate with the solid curd, but always floats in the whey, causes whey-strings, as already mentioned, and materially impairs the suppleness. If the whey be of a green colour, when loaded or pressed out, it is a certain criterion that the curd has been properly formed; but if it be of a white colour, it is equally certain that the coagulation is imperfect, the cheese will be sweet, and of little value, and much valuable caseous matter will be completely thrown away. In the counties of Norfolk and Suffolk, the cheese manufacturers have recourse to a somewhat different method for extracting the whey, which is worthy of notice. When they think the milk sufficiently coagulated, they lay a strainer in a basket made for the purpose, into which they put the curd, and suffer it to remain there for some time, so strain, before they break the curd. When the curd is sufficiently drained, it is put into two or three separate vessels, and is broken with the hand as small as

possible. During this part of the process salt is scattered over the curd, and intimately mixed with it; the proportion, however, has not been correctly ascertained, and is regulated by experience.

7034. *Management in the press.* The breaking and salting completed, a cloth is spread over the cheese vat, and the broken curd being packed into it, and covered up with the cloth, a smooth round board is laid over the vat, which is usually filled to the height of one inch above the brine, to prevent the curd from shrinking below its sides, when the whey is squeezed out.

7056. The whole of *then pinidae* is given for two hours, and as it is of the utmost importance that every drop of whey should be expressed, slavers are thrust into the cheese through the holes in the lower part of the vat to facilitate its escape. The two hours expired, the cheese is taken out and put into a vessel of warm or hot whey for an hour or two, in order to harden its skin. On taking the cheese out of the whey it is wiped dry, and when it has become cool, is wiped in a clean dry cloth, of a fine texture, and then is wrapped in a cloth of the same material, and is carried to the setting room, where it is rubbed on each side with salt; after which it is wrapped in another dry cloth of a finer texture than either of the preceding cloths, and is again pressed for twelve or fourteen hours; if any edges prove these are pinned off, and the cheese being laid upon a dry board, is turned over, and the setting room closed that the kept warm until it has had a crust, or has become regularly dry and unswollen, when it is wrapped in a cloth of the same material as the others, and is taken out to have a final appearance, which is the surest sign of superior excellence.

7056. *Management in the cheese-room.* After the processes of salting and drying are completed, the cheeses are deposited in the cheese-room or loft, which should be airy and dry but on no account should hard and soft cheeses be placed in the same room, for the dampness or moisture arising from the latter will cause the hard cheese to chill, become thick coated, and often spotted. Throughout the whole process of cheese-making, the minutest attention will be requisite, for if the whey be imperfectly expressed, or the rennet be impure, or the cheese be not sufficiently salted, it will become rank and pungent. For this defect there is no remedy. The imperfect separation of the whey will cause cheese to heave or swell, as well as to run out at the sides.

[illegible]

7028. *Hard and spoiled cheese* may be restored in the following manner: take four ounces of pearlash, and pour sweet white wine over it, until the mixture ceases to effervesce. Filter the solution, dip into it clean linen cloths, cover the cheese with them, and put the whole into a cool place, or dry cellar. Repeat this process every day at the same time turning the cheese, and if necessary continue it for several weeks. Thus the hardest and most soured cheese, it is affirmed has frequently recovered its former savor.

**SECT VI** *Catalogue of the different Sorts of Cheeses and other Preparations made from Milk.*

7059. *Of cheeses*, we shall first enumerate the British sorts, and next those peculiar to foreign countries the description of each will be such as to enable any ingenious dairymaid to imitate them.

7080 The *Swiss-cheese* cheese is so named from the form of the mould; it is formed of new milk and cream in the proportion of two gallons of the former to a quart of the latter. It is principally made in Wiltshire, in the month of September, and should not be cut until it is twelve months old.

7061 *Cheddar cheese*, so named from the vale of that name in Somersetshire, where it is exclusively made. It is made in cheeses about thirty pounds each, which have a spongy appearance, and the eyes are filled with a humped and rich, but not rancid oil.

7062, *Chester cheese* is in universal esteem. It is made from the whole of the milk and cream, the morning's milk being mixed with that of the preceding evening, previously warmed. The general weight is sixty pounds each cheese.

It is likely that cheese was first called for its having been first brought to the Glasgow market by a carrier who worked in the parish of Dunip, in Ayrshire, has been made in the district of Cunningham in Ayrshire, from time immemorial. The quality of this cheese has certainly not been equalled in any other part of Scotland, and sorely surpassed in England. According to Alison it is "milder in its taste, and fatter than any English cheese whatever." The following directions are from this author's *Dairy Household*.

2004, when a strong east wind on Jan. 25 drove so that their bodies were blown away from the shore. The birds were either winter (less a day), the mites, as it comes from the shore, is passed through a sieve (periodically turned a wheel) to remove impurities like in birds (and) and when the chicks are collected, it is removed (with) by a mixture of water and alcohol. The birds are then placed in a container at the bottom of the cage of empty, young, and as it is not used consistently during the operation of building their several nests, and in passing through the sieve, it is necessary that those who act their birds in this cultural have to make up some part of their work in late, by making a

20th. When the waves on a storm are not as numerous or as high as usual, it takes a shorter time for the water to be raised, the water is turned about six or eight inches down in the troughs and

[illegible]

7083. *Lancashire cheese* is made by adding the cream of one week's milk to that which comes immediately from the cow; it is pressed gently two or three times, and is turned for a few days previously to being used. It is chiefly made in spring, but the richest is that made in autumn. It will not keep above three months.

7084. *Stilton cheese* is made from the whey of the milk and cream; the milk is from thirty to fifty pounds; it is generally coloured yellow and is reckoned a good keeping cheese.

7085. *Butt, or slip-cheese*, is made from new milk hot from the cow, and the whey; and what is required to make one pound of butter, will, in general, make one pound of cheese: this is a small soft rich cheese, which must be used immediately.

7086. *Stilton cheese*, which, from its peculiar richness and flavour has been called the Parmesan of England, is made in the following manner:—The night's cream is put to the morning's milk with the rennet; when the curd is come, it is not broken as it would with other cheese, but is taken out whole, and put into a sieve to drain gradually while draining it is gently pressed till it becomes firm and dry when it is placed in a vat, a box made exactly to fit it, as it is so extremely rich, that without this precaution it is apt to bulge out, and break asunder. It is afterwards kept on dry boards, and turned daily with cloth binders round it, which are tightened as occasion requires. After being taken out of the vat, the cheese is closely bound with cloth till it acquires sufficient firmness to support itself; when these cloths are removed, each wheen is brushed once every day for two or three months, and if the weather be moist, twice every day the tops and bottoms are treated in a similar manner daily before the cloths are taken off. Stilton cheese derives its name from the town where it is almost exclusively sold. It is made principally in Leicestershire, though there are also many who manufacture it in the counties of Huntingdon, Rutland, and Northampton. Sometimes the cheeses are made in a net, resembling a cabbage net, which gives them the form of an onion: but these are neither so good nor so richly flavoured as those made in vats, having a thicker coat, and being deficient in that mellowness which causes them to be in such general request. (*Both Papers*, vol. ii. p. 152, 153.) Stilton cheese is not reckoned to be sufficiently mellow for eating until it is two years old, and it is not saleable unless it is decayed, blue, and moist. In order to mature them the more rapidly it is a frequent practice to place one cheese on another, which are covered over with horse-dung. Wine is also reputed to be added to the curd, in order to accelerate the ripening of the cheese.

7087. *Cheshire cheese*, from the town of that name in Cambridgeshire, is a thicker kind of cream cheese than the Stilton. Its superior delicacy and flavour are attributed to the fragrant nature of the herbage on the commons on which the cows are pastured, and, according to Professor Martyn, to the prevalence of *Faba aquatica* and *pratensis*.

7088. *Swiss, or alpine cheese*, is made of skimmed milk; it forms a part of every ship's stores, not being so much affected by heat as richer cheese, nor so liable to decay in long voyages.

7089. *Wiltshire cheese* is made of new milk coagulated as it comes from the cow: sometimes a small quantity of skimmed milk is added. In some districts it is manufactured in winter as well as summer; in the former case it is liable to become scurvy and white coated; the last of which defects is frequently concealed by a coat of red paint.

7090. *Of foreign cheeses*, the most common is the *Dutch cheese*; this is prepared much in the same manner as the Cheshire cheese, excepting that lactic acid is used instead of rennet, which renders it pungent, and preserves it from mites: that of Gouda is preferred.

7091. *Parmesan cheese* (*formaggio di grana*, cheese used in a granular form,) is made in the Duchy of Parma, and in various places in Lombardy. It was formerly supposed to be made from the milk of goats, but it is merely a skim-milk cheese, the curd hardened by heat, well salted, pressed, and dried, long kept, and rich in flavour from the rich herbage of the meadows of the Po, where the cows are pastured.

7092. The process, according to Pagan, (*Both Papers*, vol. vi.) is as follows:—The morning's milk being skimmed, and the evening's milk skimmed about two hours after it is drawn from the cow are mixed together. The mixture is then assembled in a copper cauldron over a wooden fire (*fig. 35*), and frequently stirred till it attains about 17° of Fahrenheit; the rennet is then put in, and the curd being removed from the fire, the coagulation quickly takes place, and the curd is afterwards worked with stick till it is reduced to small grains. The whey now occupies the surface, and a part of it being taken out, the cauldron is again turned over the fire, and its contents brought to nearly boiling heat. A little salt is now added to impart colour; the whole being all the while well stirred, and the superfluous skimming it from time to time with his finger and thumb, to ascertain the exact moment when the curd shall have become sufficiently solid. When this is the case, the cauldron is removed from the fire, and the curd allowed to settle; these flourish of the whey is then drawn off, water poured round the bottom of the cauldron outside to and to, so as to admit of a cloth being passed below the curd, which is then brought up and placed in salt to clear. When drained, it is put into wooden hoops, and about half a hundred weight laid on it for half an hour; the cloth is then removed, and the cheese being exposed in the hoop is laid on cloth; here it remains for two or three days, at the end of which it is quenched over with salt; this salting is repeated every second day for about thirty days if it be autumn, and for about thirty or thirty-five days if it be winter, after which no further attention is required. The best Parmesan cheese which has been kept for three or four years, but more is now wanted to market for sale which it has been kept at least six months. A short account of a Parmesan cheese factory situated between Milan and Milan, is given in *Cook's Journal* in *Cook's* vol. 111, and quoted in *Pagan*, *Agar*, vol. xii. p. 161. The process is then carried on in conformity with what is above stated.

7093. *Swiss cheese* is of several varieties: mostly of skimmed or partially skimmed milk, and matured like the Parmesan. Its varied and rich flavour is more owing to the herbage of the pastures than the mode of making; and some sorts, as the Gruyère (so called from the burgh of that name in the canton of Fribourg) are flavoured by the dried herb of *Melilotus officinalis* (*fig. 43*) in powder. Gruyère cheeses weigh from forty to sixty pounds each and are packed in casks containing ten cheeses each, and exported to the most distant countries. This cheese requires to be kept in a damp place, and should frequently be washed with white wine, to preserve it from the depredations of insects. Neuchâtel is celebrated for a very fine sort of cheese made there, which, in shape, resembles a wash-bowl.

7094. *Wasserkäse* cheese is of the skim-milk kind, and of a different character from any of those hitherto described. The cream is allowed to remain on the milk till the latter is in a subacid state, it is then removed, and the milk placed near a fire spontaneously to coagulate. The curd is then put into a coarse bag, and loaded with ponderous stones to express the whey: in this dry state it is rubbed between the hands, and crumbled into an empty clean milk vat where it remains from three to eight days, according as the cheese is intended to be strong or mild. During this part of the process, which is called mellowing, the curd undergoes the putrid fermentation, and acquires a coat or skin on the top, before it is taken out of the vessel, and kneaded into balls or cylinders, with the addition of a considerable portion of butter, salt, and butter; or occasionally a small quantity of pounded pepper and cloves. When oven-mellowed, a third part of fresh curd, likewise crumbled into small pieces, is superadded, to prevent or correct its putrid tendency. As the balls or cheeses do not exceed three or four ounces each in weight, they soak dry in the open air, and are then fit for use. When nearly dry they are sometimes, for the purpose of salting, suspended in a wood-fire chimney in a net, for several weeks or months; and both their taste and flavour are said to be remarkably improved, whether kept in a dry air or subjected to the action of smoke. The sort of cheese Mr. Hohenheimer, who describes it, affirms to be preferable to the Dutch, Swiss, and even Parmesan cheese. It is sometimes to be had in London, but is not very common.

7095. *Blue made cheese* is made in the neighbourhood of Edinborough, by Mr. Johnston, of Hill House. It is similar to the Stilton to which it is said to be not inferior. Mr. Johnston never sells his curd into cheese press, but into a bag or net, in which it is suspended, and frequently washed, till it is sufficiently dry and solid. The cheeses are small about five or six pounds each.

7099. *Polish cheese* is a German manufacture, of which there are three sorts. One of the best is thus prepared—Select evenly potatoes, and only half dress them in steam for by leaving their skins and allowing unchopped. Peel them, and then grate or beat them into a fine pulp. To three parts of this mass add two parts of sweet curd, knead and mix them and allow them to stand three days in water, and stir or five days in cold weather. Form into small pieces like the Westphalia cheeses, and dry in the same manner. A still better sort of potato cheese is formed of one part of potatoes and three of the curd of sheep's milk. This sort is said to exceed in taste the best cheese made in Holland, and to possess the additional advantage that it improves with age, and generates no vermin.

7097. *The preparations of milk* which can neither be included under butter nor cheese, are various, and constitute a class of wholesome luxuries or rural drinks. We shall do little more than enumerate them, and refer for farther details to the cookery books.

7098. *Curd and whey* is merely coagulated new milk stirred up, and the curd and whey eaten together with or without sugar and salt.

7099. *Curd and cream* have the whey removed and cream substituted, with or without sugar. The milk coagulated is often previously skimmed.

7100. *Sour cream* cream allowed to stand in a vat till it becomes sour when it is eaten with fresh cream and sugar, or new milk and sugar and is found delicious.

7101. *Devonshire cream*, so named from a village of that name, two miles from Exmouth, from which the latter city is supplied with it. The milk of three or four days is put together with the cream, till it begins to get sour and coagulated, when the whey is drawn off and fresh cream added. It is, therefore, simply *sour curd* and *fresh cream*. It is eaten with sugar as a supper dish, and in great repute in the north.

7102. *Devonshire cream* is a term applied in the county of that name sometimes to *sour curd*, and sometimes to *sour cream*. In either case mixed with new milk or fresh cream, and eaten with sugar like the *Devonshire cream*.

7103. *Devonshire acidulated or clotted cream*. The milk is put into tin or earthen pans, holding about ten or twelve quarts each. The evening's meal is placed the following morning, and the morning's milk is placed in the afternoon, upon a broad iron plate heated by a small furnace, or otherwise over stoves, where, exposed to a gentle fire, they remain until after the whole body of cream is supposed to have formed upon the surface which being gently removed by the edge of a spoon or ladle, small air bubbles will begin to rise that denote the approach of a boiling heat, when the pans must be removed from off the heated plate or stove. The cream remains upon the milk in the state until quite cold, when it may be removed into a churn, or, as is more frequently the case, into an open vessel and then moved by hand with a stick about a foot long at the end of which is fixed a sort of pad from four to six inches in diameter and with which about twelve pounds of butter may be separated from the buttermilk at a time. The butter in both cases being found to separate much more freely and sooner to coagulate into a mass, than in the ordinary way, where churned from raw cream that may have been several days in gathering and at the same time will answer a more valuable purpose in preserving, which should be first altered in the usual way then placed in convenient-sized egg-shaped earthen crocks, and always kept covered with a weak, made strong enough to float and being up about half out of the brine a new laid egg. This cream, before churning, is the celebrated clotted cream of Devon. Although it would be reasonable to suppose that the churning the milk must have occasioned the whole of the oily or unctuous matter to form on the surface, still experience shows that this is not the case, and that the acidulated skim-milk is much richer and better for the purposes of cooking and makes far better cheese than the raw skim milk does. The ordinary produce of milk per day for the first twenty weeks after calving, is three gallons, and is equal to the produce of one pound and a quarter of butter daily by the churning process. The solid skim milk is valued at one penny farthing per quart, either for cheese-making or feeding hogs. The sum of the trials practised to be made on the milk in several parts of the district gives an average of twelve pints of milk to ten ounces of butter (less than ten quarts to a pound of sixteen ounces). When cheese is to be made, *great care* is taken that the milk is not heated so far as to produce bubbles under the cream. (*Farmer's Repository of Devon*, p. 515.)

7104. *Clotted milk*. The milk, when drawn from the cow is suffered to remain in the cooler till it begins to get sour and the whole is coagulated. It is then stirred and the whey drawn off, or the cream (now in clots among the curd) and the curd removed.

7105. *Heated milk*. A gallon of sour buttermilk is put in the bottom of the milk-pail, and a quart or more of milk drawn from the cow into it by the milk maid. The new warm milk, as it mixes with the end of the sour milk, coagulates, and being lighter rises to the top and forms a creamy scum or hat over the other, whence the name. This surface stratum is afterwards taken off and eaten with sugar.

7106. *Milk agitated* is formed in a similar manner over a glass or two of wine, and the whole is then eaten with sugar. Both sorts may be formed by those who have no cow by warming the sweet or new milk, and squirting it into the wine or sour milk.

7107. *Skim-milk* is milk from which the cream has been removed. When this has been done within twelve or fifteen hours from the time of milking, it is sweet and wholesome, and fit either for being heated or coagulated in order to make cheese, &c. or used as it is with other food but if allowed to remain twenty or thirty hours, it becomes sour coagulates spontaneously the whey separates from the curd; and if it remain a certain period, generally three weeks longer in a warm temperature, the various fermentation takes place, and a wine or a liquor, from which ardent spirit may be distilled, is produced.

7108. *Buttermilk* is that which remains in the churn after the butter has been taken off. When butter has been made from cream alone, it is seldom of much value but where the whole milk has been churned, and no water poured in during the process, it is a very wholesome cooling beverage. Some prefer it when it has stood a few days and becomes sour. In England it is chiefly given to pigs but in Ireland it forms a very common diet for porridge, potatoes, oat cakes, peas cakes, and other food of the labouring classes, and especially of the farm servants. In the Orkney Islands and other northern parts of Britain, as well as in Ireland, buttermilk is sometimes kept till it undergoes the various fermentations, when it is used to produce intoxication.

7109. *Sour milk*. Aston observes, requires considerable care in the manufacturing, and the use of the thermometer ought never to be omitted. "When the operation is carried on at a low temperature the milk smells when agitated in the churn, appears of a white colour throws up air bubbles, and makes, when agitated or churned, a rattling noise. But when it is in proper temperature the milk does not swell or rise in the churn, it is of a grey or cream colour emits a much richer sound, and does not cast up air bubbles so plentifully as when colder. When milk is either overheated or churned too hastily the butter is always wet and of a white colour. From two to three hours is a proper time for performing the operation of churning. In the manufacture of sour milk, and in every branch of dairy husbandry the utmost attention to cleanliness is indispensably necessary. The milk must no doubt become sour, and even coagulate before it is churned; but if that souring is not natural, but brought on by any impurities in the vessels through which the milk passes, or by any sort of admixture, or even by the milk being kept in a damp place, in sun too hot or too cold, or even by exposure to an impure atmosphere, the acidity will not be a natural one, nor the taste of the milk or butter agreeable, but acid and unpalatable. Every vessel through which the milk passes must be as clean, and every part where it is kept before being churned must be as free from dampness, and every species of impurity or bad air as if it were intended to keep the

milk long sweet for cheese. Buttermilk is used, more or less by the following classes in all parts of Scotland, and in particular in the city of Glasgow:—as the authority of the parsonry to the Board of Agriculture, it is assigned to the pigs in England; but in the western counties of Scotland, as well as in Ireland, it is used to a vast extent as human food. It is used as *crème*, and is certainly not superior to the miserable table-butter generally drunk in England. It comes as *crème* in pottages, bread, potatoes, &c.; and when a linen bag like a pillow-cup is filled with it, and hung up till the serum drop, and a small quantity of sweet cream is mixed with what remains in the bag, and a little sugar when the milk is too sour it forms a dish that might be placed on the table of a pair of the realm.

7113. The method of making butter and buttermilk in Holland is somewhat different from the mode in the vicinity of Glasgow. After the milk is sold it is put into a pan or vat, and well stirred with a wooden spoon or loddle two or three times a day to prevent the cream from separating from the milk; and this sort of stirring or partial churning is continued till the milk becomes so thick and clotted that the loddle or spoon stands erect in the milk; after which it is put into the churn, and beat or churned for one hour or so. Cold water is poured in, to help to collect the butter and separate the milk from it; after which the butter is washed in cold water. By this method the Hollanders imagine they obtain more butter from the milk than they can do any other way. They also say, that both the butter and buttermilk are better when made in this way than when churned as is done in England.

7111. *Whisky*, when new and of a pale green colour forms an agreeable beverage, and with oatmeal makes an excellent gruel or porridge. Left till it gets sour it undergoes the vinous fermentation as readily as buttermilk. And man, who in every state of civilization feels the necessity of occasionally stimulating the curve of his mind, when he cannot find tobacco, opium, malt liquor, or ardent spirit, has recourse to sour whisky.

## CHAP. VI.

*The Sheep.* — *Ovis Aries* L. *Moschus Moschus* L. and *Ruminans* Cuv. *Britia*, Fr.; *Schaf*; Ger. *Oveja*, Span., and *Pecora*, Ital.

7112. *The sheep* is an inhabitant of every part of the globe, from Iceland to the regions of the torrid zone. The varieties of form and clothing necessary to fit it for existing in so many climates are of course numerous. In most of these countries it is cultivated for its wool or flesh, and in many for both; but it is most cultivated in Europe, and especially in France, Spain, and Britain. In the latter country its culture has attained an astonishing degree of perfection. Besides the *O. Aries*, or common sheep, there are three other species the *O. Ammon* or Siberian sheep, the *Padus* or South American, and the *Strepsiceros* or Cretan sheep. By some these are considered mere varieties. The Cretan and Siberian are cultivated in Hungary and Siberia.

7113. *The common sheep* is a wild state prefer open plains, where they herd together in small flocks, and are in general active, swift, and easily frightened by dogs or men. When completely domesticated, the sheep appears as stupid as it is harmless. It is characterised by Buffon as one of the most timid, insensible, and contemptible of quadrupeds. When sheep, however have an extensive range of pasture, and are left in a considerable degree to depend on themselves for food and protection, they exhibit a more decided character. A ram has been seen in these circumstances to attack and beat off a large and formidable dog. Sheep display considerable sagacity in the selection of their food, and in the approach of storms they perceive the indications with accurate precision, and retire for shelter always to the spot which is best able to afford it. The sheep is more subject to diseases than any of the domesticated animals. *Phtisis*, consumption, scab, droupy and worms frequently seize upon and destroy it. That popularity called the rot is the most fatal, and is supposed to arise from the existence of animals called fluke worms, of the genus *Fasciola*, which inhabit the vessels of the liver. Other parasitic animals attack and injure them, as the hydatids within the skull, producing symptoms called sturdy, turnback, staggers, &c. Frontal worms, deposited by the sheep fly, in some cases prove very injurious also.

7114. *Of all the domestic animals of Britain*, Brown observes, *sheep are of the greatest consequence*, both to the nation and to the farmer; because they can be reared in situations, and upon soils, where other animals would not live, and in general afford greater profit than can be obtained either from the rearing or feeding of cattle. The very fleece shorn annually from their backs, is of itself a matter worthy of consideration, affording a partial return not to be obtained from any other kind of stock. Wool has long been a staple commodity of this island, giving bread to thousands who are employed in manufacturing it into innumerable articles for home consumption and foreign exportation. In every point of view sheep husbandry deserves to be esteemed as a chief branch of rural economy, and claims the utmost attention of agriculturists. For many years back it has been studied with a degree of diligence and assiduity not inferior to its merits, and the result has been, that this branch of rural management has reached a degree of perfection favourable to those who exercised it, and highly advantageous to the public.

### SECT. I. Varieties of Sheep.

7115. *The varieties of the O. Aries*, or common sheep, dispersed over the world are, according to Linnæus, the hornless, horned, blackfaced, Spanish, many-horned, African, Gynæa, broad-tailed, fat-rumped, Bucharian, long-tailed, Cape, bearded, and morvant; to which some add the Siberian sheep, cultivated in Asia, Barbary, and Cornea, and the Cretan sheep, which inhabits the Grecian islands, Hungary and Austria, by Linnæus considered as species.

7116. *The varieties of British sheep* are so numerous that at first sight it appears almost impossible to reduce them into any regular classes. They may, however, be divided in two ways first, as to the length of their wool and secondly, as to the presence or absence of horns. A third classification might be made after the place or districts in which such species are supposed to abound, to be in greatest perfection, or to have originated.

7117 The long-woolled British sheep are chiefly the \* Teeswater, the \* old and \* new Leicesters, the \* Devonshire note, Exmoor and the Heath sheep.

7118 The short-woolled sheep are chiefly the Dorsetshire, \* Hereford or Ryeland, the \* South Down, the Norfolk, the \* Cheviot, the \* Shetland sheep, and the \* Merinos.

7119 The hornless breeds are those in the above classes marked (\*), the others have horns. These breeds, and their subvarieties, may be further arranged according as they are suited to arable or enclosed lands, and to open or mountainous districts.

7120 The sheep best suited to arable land, an eminent writer observes, in addition to such properties as are common in some degree to all the different breeds, must evidently be distinguished for their quietness and docility habits which, though gradually acquired and established by means of careful treatment, are more obvious, and may be more certainly depended on in some breeds than in others. These properties are not only valuable for the sake of the fences by which the sheep are confined, but as a proof of the aptitude of the animals to acquire flesh in proportion to the food they consume.

7121 The long-woolled large breeds are those usually preferred on good grass-lands; they differ much in form and size, and in their fattening quality as well as in the weight of their fleeces. In some instances, with the Lancashire or old Leicesters in particular, wool seems to be an object paramount even to the carcass, with the breeders of the Leicesters, on the other hand, the carcass has always engaged the greatest attention but neither form nor fleece, separately is a legitimate ground of preference the most valuable sheep being that which returns, for the food it consumes, the greatest marketable value of produce.

7122 The Lincolnshire or old Leicestershire breed, have no horns, the face is white and the carcass long and thin the ewes weighing from 14 to 20 lbs. and the three-year-old wethers from 20 to 30 lbs. per quarter. They have thick, rough, white legs, bones large, pelts thick, and wool long from ten to eighteen inches, weighing from 5 to 14 lbs. per fleece, and covering a slow-flesking, coarse-grained carcass of mutton. This kind of sheep cannot be made fat at an early age except upon the richest lands, such as Romney Marsh and the richest marshes of Lincolnshire; yet the prodigious weight of wool which is shorn from them every year is an inducement to the occupiers of marsh-lands to give great prices to the breeders for their hops or yearlings, and though the buyers must keep them two years more before they get them fit for market, they have three clips of wool in the mean time, which of itself pays them well in these rich marshes. Not only the midland counties, but also Yorkshire, Durham and Northumberland, can send their long-woolled sheep to market at two years old, fatter in general than Lincolnshire can at three. Yet this breed, and its subvarieties, are spread through many of the English counties.

7123 The Teeswater sheep (Fig 883) differ from the Lincolnshire in their wool not being so long and heavy, in standing upon higher though finer boned legs, supporting a thicker, firmer, heavier carcass, much wider upon their backs and sides; and in affording a fatter and finer grained carcass of mutton the two-year-old wethers weighing from 25 to 35 lbs. per quarter. Some particular ones, at four years old have been fed to 55 lbs. and upwards. There is little doubt that the Teeswater sheep were originally bred from the same stock as the Lincolnshire but, by attending to size rather than to wool, and constantly purving that object, they have become a different variety of the same original breed. (*Culling on Live Stock*, p. 132.) The present fashionable breed is considerably smaller than the original species but they are still considerably larger and fuller of bone than the midland breed.

They bear an analogy to the short-horned breed of cattle, as those of the midland counties do to the long-horned. They are not so compact, nor so complete in their form, as the Leicestershire sheep nevertheless, the excellence of their flesh and fattening quality is not doubted, and their wool still remains of a superior staple. For the banks of the Tees, or any other rich fat-land county they may be angularly excellent.

7124 The Dishley, or new Leicester breed (Fig 884) is distinguished from other long-woolled breeds by their clean heads, straight broad, flat backs, round barrel-like bodies, very fine small bones, thin pelts and inclination to make fat at an early age. This last property is most probably owing to the before-specified qualities, and which, from long experience and observation there is reason to believe extends through every species of domestic animals. The Dishley breed is not only peculiar for its mutton being fat, but also for the fineness of the grain, and superior flavour above all other large long-woolled sheep, so as to fetch nearly as good a price, in many markets, as the mutton of the small Highland and short-woolled breeds. The weight of ewes, three or four years old, is from 15 to 25 lbs. a quarter, and of wethers, two years old, from 20 to 30 lbs. The wool, on an average, is from 6 to 8 lbs. a fleece. (*Culling* p. 103.)

7125 The Devonshire Note (Fig 884) have white faces and legs thick necks, narrow backs, and back-bone high; the sides good, legs short, and the bones large weight such the same as the Leicesters, wool heavier but coarser. In the same country there is a small breed of long-woolled sheep known by the name of the *Sammer* sheep, from the place where they are chiefly bred. They are horned, with white faces and legs, and peculiarly delicate in bone, neck, and head; but the form of the carcass is not good, being narrow and flat-sided. The weight of the quarters, and of the fleece, about two thirds that of the former variety.

7126 The shorter-woolled varieties, and such as, from their size and form, seem well suited to hilly and inferior pastures, are also numerous. Generally speaking, they are too restless for enclosed arable land, on the one hand, and not sufficiently hardy for healthy mountainous districts, on the other.

To this class belong the breeds of Dorset, Hereford, Sussex, Norfolk, and Cheviot.

7187. *The Dorsetshire sheep* (fig. 885) are mostly horned, white faced, stand upon high small white legs, and are long and thin in the carcass. The wethers, three years and a half old weigh from 15 to 20 lbs. a quarter. The wool is fine and short, from 5 to 6 lbs. a fleece. The mutton is fine grained and well flavoured. This breed has the peculiar property of producing lambs at almost any period of the year, even so early as September and October. They are particularly valued for supplying London and other markets with house lambs, which is brought to market by Christmas or sooner if wanted, and after that a constant and regular supply is kept up all the winter.

shire, Herefordshire, &c. though some of them are very different from the Dorsetshire, yet they are, in all respects, only variations of this breed, by crossing with different tops; and which variations continue northward until they are lost amongst those of the Lincolnshire breeds. (Cuddey p. 131)

7188. *The Herefordshire breed* (fig. 886) is known by the want of horns, and their having white legs and faces, and the wool growing close to their eyes. The carcass is tolerably well formed, weighing from 10 to 18 lbs. a quarter and being very fine short wool, from 1½ to 2½ lbs. a fleece. The mutton is excellent. The store or keeping sheep of this breed are put into coats at night, winter and summer, and in winter foddered in racks with pea-straw barley-straw &c. and in very bad weather with hay. These coats are low buildings, quite covered over and made to contain from one to five hundred sheep, according to the size of the farm or flock kept. The true Herefordshire breed are frequently called *Ryeland* sheep, from the land formerly being thought capable of producing no better grain than rye but which now yields every kind of grain. A cross between this breed and the merinos was extensively cultivated by the late Dr. Farry of Bath an eminent wool grower and promoter of agricultural improvement.

7189. *The South Down sheep* (fig. 887) are without horns they have dark or black-grey faces and legs, fine bones, long small necks; are low before, high on the shoulder and light in the fore-quarter; the sides are good, and the loin tolerably broad back-bone too high, the thigh full, and twist good. The fleece is very short and fine, weighing from 2½ to 3 lbs. The average weight of two years old wethers is about 16 lbs. per quarter, the mutton fine in the grain, and of an excellent flavour. These sheep have been brought to a high state of improvement by Elman of Glynd, and other intelligent breeders. They prevail in Sussex on very dry chalky downs, producing short fine herbage.

7190. *The Norfolk sheep* the face is black, horns large and spiral, the carcass is very small, long thin, and weak, with narrow chines, weighing from 15 to 20 lbs. per quarter and they have very long dark or grey legs, and large bones. The wool is short and fine from 1½ to 2 lbs. per fleece. This race have a voracious appetite, and a restless and unquiet disposition, which makes it difficult to keep them in any other than the largest sheep-walks or commons. They prevail most in Norfolk and Suffolk and seem to have been retained chiefly for the purpose of folding. As fatteners, they are not profitable; but the mutton produced is inferior to none. A three or four year old Norfolk wether will produce a haunch, which if kept two or three weeks, will vie with that of any animal excepting a buck.

7191. *The Cheviot breed* are without horns, the head bare and clean, with jaws of a good length faces and legs white. The body is long, but the fore-quarters generally want depth in the breast, and breadth both there and so the spine though in these respects, great improvement has been made of late. They have fine, clean, small-headed legs, well covered with wool to the hough. The weight of the carcass, when fat, is from 13 to 15 lbs. per quarter their fleece, which is of a medium length and fineness, weighs about 3 lbs. on an average. Though these are the general characters of the pure Cheviot breed many have grey or dun spots on their faces and legs, especially on the borders of their native districts, where they have intermixed with their black-faced neighbours. On the lower hills, at the extremity of the Cheviot range, they have been frequently crossed with the Leicesters, of which several flocks, originally Cheviots, have now a good deal both of the form and fleece. The best kind of these sheep are certainly a very good mountain stock, where the pasture is mostly green sward, or contains a large portion of that kind of herbage, which is the case of all the hills around Cheviot, where these sheep are bred. Large flocks of them have been sent to the Highlands of Scotland, where they have succeeded so well as to encourage the establishment of new colonies; yet they are by no means so hardy as the heath or black-faced kind, which they have, in many instances, supplanted.

7192. *Of those races of sheep that range over the mountainous districts of Britain*, the most numerous, and the one probably best adapted to such situations, is the *heath* breed, distinguished by their large spiral horns, black faces and legs, fierce wild-looking eyes, and short, firm carcasses, covered with long, open, coarse shaggy wool. Their weight is from 10 to 16 lbs. a quarter, and they carry from 3 to 4 lbs. of wool each. They are seldom fed until they are three, four, or five years old, when they fatten well, and give excellent mutton and highly flavoured gravy. Different varieties of these sheep are to be found in all the western counties of England and Scotland, from Yorkshire northwards, and they want nothing but a fine fleece to render them the most valuable upland sheep in Britain.

7193. *The Hardwick sheep* (fig. 888) are peculiar to that rocky mountainous district at the head of the Duddon and Rib rivers, in the county of Cumberland. They are without horns, have speckled faces and legs, wool short, weighing from 2 to 2½ lbs. per fleece, which, though coarser than that of any of the other short-wooled breeds, is yet much finer than the wool of the heath sheep. The mountains upon which the Hardwicks are bred, and also the stock itself, have, time immemorial, been famed out to herds, and from this circumstance their name is derived.

7194. *The dun-faced breed*, said to have been imported into Scotland from Denmark or Norway at a very early period, still exists in most of the counties to the north of the Firth of Forth, though only in very small flocks. Of this ancient race there are now several

varieties, produced by peculiarities of situation, and different modes of management, and by occasional intermixture with other breeds. We may, therefore, distinguish the sheep of the mainland of Scotland from those of the Hebrides, and of the northern islands of Orkney and Shetland.

7185. *The Hebridean sheep* is the smallest animal of its kind. It is of a thin, lank shape, and has usually straight shorn horns. The face and legs are white, the tail very short, and the wool of various colours; sometimes of a bluish grey, brown, or deep russet, and sometimes all these colours meet in the fleece of the animal. When the pasture and management are favourable, the wool is very fine, resembling in softness that of Shetland; but, in other parts of the same islands, the wool is matted and coarse, the animal sickly and gaunt, and frequently carries four or even six horns. The average weight of this poor breed, even when fat, is only 5 or 5½ lbs. per quarter or nearly about 20 lbs. per sheep. It is often much less, only amounting to 15 or 16 lbs. and the price of the animal's carcass, skin and oil, is from 10s to 14s. Fat wethers have been sold in the Long Island at 7s a head, and ewes at 5s or 6s. The quantity of wool which the fleece yields is equally contemptible with the weight of the carcass. It rarely exceeds one pound weight, and is often short of even half that quantity. The quality of the wool is different on different parts of the body, and attention to separating the fine from the coarse, renders the cloth made in the Hebrides very unequal and precarious in its texture. The average value of a fleece of this shaggy Hebridean breed is from 6d to 1s sterling. From this account it is plain, that the breed in question has every chance of being speedily extirpated. (*Macdonald's Report of the Hebrides*, p. 467.)

7187. *Of the Orkney sheep* it would appear that there are two varieties, one of which is considered to be the native race, and carries very fine wool, but the number of these is much diminished, and in some places they have been entirely supplanted by foreign breeds: the other variety carries coarse wool above, and soft fine wool below. They have three different successions of wool yearly: two of which resemble long hair more than wool, and are termed by the common people, *fine* and *scudde*. When the wool begins to loosen in the roots, which generally happens about the month of February the hairs, or scudde, spring up: and when the wool is carefully plucked off, the tough hairs continue fast until the new wool grows up about a quarter of an inch in length: then they gradually wear off: and when the new fleece has acquired about two months' growth, the rough hairs, termed *fine*, spring up and keep root until the proper season for pulling it arrives, when it is plucked off along with the wool, and separated from it, at drawing the fleece, by an operation called *finning*. The scudde remains upon the skin of the animal, if it were a thick coat, a fleece against the inclemency of the seasons which provident nature has furnished for supplying the want of the fleece. The wool is of various colours: the silver grey is thought to be the finest, but the black, the white, the mottled, or brown, is very little inferior: though the pure white is certainly the most valuable for all the finer purposes in which combing wool can be used. (*See John Smollett on the different Breeds of Sheep*, 8c. Appendix No. 4. *Account of the Shetland Sheep*, by Thomas Johnston, p. 78.) In the northern part of Shetland-shire, as well as in most other of the northern counties, there is still a remnant of the ancient race, distinguished by the yellow colour of the face and legs, and by the dishevelled texture of the fleece, which consists in part of coarse, and in part of remarkably fine wool. Their average weight in that county is from seven to nine pounds a quarter: and the wethers are remarkably delicate and highly favoured. (*King'sburgh's Report*, p. 365. *See E. Brit. art. Agr.* 176.) The Highland Society of Scotland have selected seven rams for the improvement of this breed, and some experiments are now in progress. See vol. vi. of their *Transactions*: and for a particular account of the breed itself and its management, see *Barrow's Survey of Orkney and Shetland*.

7188. *The Spanish, or Marino breed*, bears the finest wool of the sheep species: the

males (fig. 889) usually have horns of a middle size, but the females (fig. 890) are frequently without horns: the faces and legs are white, the legs rather long, but the bones fine. The average weight per quarter of a tolerably fat ram is about seventeen pounds, and that of ewes about eleven pounds.

7189. *The sheep of this race* is far from being perfect, according to the ideas of English breeders, with whose symmetry of proportion constitutes a principal criterion of excellence. The throatiness, or pendulous skin beneath the throat, which is usually accompanied with a sinking or hollow in the neck, presents a most offensive appearance, though it is much esteemed in Spain, as denoting both a tendency to fine wool, and a heavy fleece. Yet the Spanish sheep are level on the back, and behind the shoulders: and Lord Somersville has proved that there is no reason to conclude that deformity in shape is, in any degree, necessary to the production of fine wool.

7190. *The fleece of the Marino sheep weighs*, upon an average, from three to five pounds: in colour it is unlike that of any English breed: there is on the surface of the best Spanish fleeces a dark brown tinge, approaching almost to a black, which is formed by dust adhering to the greasy properties of its pile: and the contrast between this tinge and the rich white colour below, as well as that fiery hue of the skin which denotes high proof, at first sight excites much surprise. The harder the fleece is, the more it reveals any external pressure of the hand, the more close and fine will be the wool: here and there, indeed, a fine pile may be found in an open fleece, though this occurs but rarely. Nothing, however, has tended to render the Marino sheep more unsightly to the English eye than the large tuft of wool which covers the head: it is of a very inferior quality and clames with what is produced on the hind legs; on which account it does not sort with any of the three qualities, viz. *refined* or prime *fine*, or second best: and, therefore, the inferior sort, and, consequently is never exported from Spain.

7191. *Marino ewes first brought into England* in 1786, but did not excite much interest before his Majesty's sales, which began in 1804: the detestable aspect of spreading them widely over the country and subjecting them to the experiments of the most eminent professional breeders, has been greatly promoted by the institution of the Marino Society in 1811, to which belonged some of the greatest landowners, and the most eminent breeders in the kingdom. For some years past, this breed has been on the decline. (*See E. Brit. art. Agr.*) A considerable importation was made by Colonel Dornie, of Paisley, which distributed the breed throughout different parts of Scotland. See the *Scottish Survey*. It is not understood that they have answered the expectations that were once formed of them: and I am not aware that there are any flocks in the possession of rent-paying farmers. The only successful experiment in Scotland seems to have been that of the late Mr. Malcolm Laing, in the Orkney Islands: and it is not the pure race, but crosses into other breeds. See the *General Report of Scotland*, vol. III.

## SECT. II. Criteria of Properties in Sheep.

7192. *The criteria of an excellent ram*, as given by Colley, combine qualities which ought to be found in every breed of sheep cultivated for its flesh and wool. His head should be fine and small: his nostrils wide and expanded; his eyes prominent, and rather held or daring: ears thin: his under full from his breast and shoulders, but tapering gradually all the way to where the neck and head join, which should be very

fine and graceful, being perfectly free from any coarse leather hanging down; the shoulders broad and full, which must, at the same time, join so easy to the collar forward and shins backward as to leave not the least hollow in either place; the scapula upon his arm or fore-shin must come quite to the knee; his legs upright, with a clean fine bone, being equally clear from superfluous skin and coarse hairy wool from the knee and hough downwards; the breast broad and well formed, which will keep his fore-legs at a proper wideness; his girth or chest full and deep, and instead of a hollow behind the shoulders, that part, by some called the flow-blank, should be quite full; the back and loins broad, flat, and straight, from which the ribs must rise with a fine circular arch; his belly straight, the quarters long and full, with the mutton quite down to the hough, which should neither stand in nor out; his twist, or junction at the inside of the thighs, deep, wide, and full, which with the broad breast, will keep his four legs open and upright; the whole body covered with a thin felt, and that with fine, bright, soft wool.

7143. The *counters* of a sound healthy sheep are, a rather wild or lively brackness; a brilliant clearness in the eye; a florid ruddy colour on the inside of the eyelids, and these are termed the *counters*, as well as in the gums; a *fastness* in the teeth; a sweet fragrance in the breath; a dryness of the nose and eyes; breathing easy and regular; a coolness in the feet; dung properly formed; coat or fleece firmly attached to the skin, and unbroken; the skin exhibiting a florid red appearance, especially upon the brisket. Where there are discharges from the nose and eyes, it indicates their having taken cold and should be attended to by putting them in dry sheltered situations. This is a necessary precaution also in bringing them from one situation to another while on the road.

7144. The *condition of the age of sheep* is the state of their teeth, by their having, in their second year two broad teeth, in their third year four broad teeth in their fourth year six broad teeth, and in their fifth year eight broad teeth before. After which, none can tell how old a sheep is while their teeth remain, except by their being worn down. About the end of one year rams, wethers, and all young sheep, lose the two fore-teeth of the lower jaw; and they are known to want the unclawed teeth in the upper jaw. At eighteen months, the two teeth joining to the former also fall out, and at three years, being all replaced, they are even and pretty white. But as these animals advance in age, the teeth become loose, blunt, and afterwards black. The age of all horned sheep may also be known by their horns which show themselves in their very first year and often at the birth and continue to grow a ring annually to the last period of their lives.

7145. The *different ages and conditions of sheep* have different names in different districts. After being weaned, the ram, or wether lamb, is sometimes termed hog, hoggit, or tag, during the whole of the first year; and the female lamb, an ewe, or glimmer lamb, and ewe tag. The second year the wether has the title of shear hog, or a two-toothed tag, and the ewe is called a thave, or two-toothed ewe. In the third year a shear hog or four-toothed wether, and a four-toothed ewe or the *va*. The fourth year, a six-toothed wether, or ewe, and in some places, from the time of lambing till that of shearing, the males are called *top-lambs*; and from that period, till the time of shearing, top-hogs, and even afterwards, tops the females in the same order being termed, ewe-lambs, ewe-hogs, glimmers, young ewes, old ewes. The gelded male lambs, castrated wether lambs, wether hogs, glimmers, wethers. Cries also signify old ewes and there are several other provincial names, which are explained in their proper places.

### SECT. III. *Breeding of Sheep.*

7146. In the breeding of sheep a greater degree of perfection has been attained than in any other live stock and in this branch, in particular, the breeders of England stand higher than those of any other country.

7147. Bakewell, by careful selection during several generations, raised his stock to a state of excellence, in regard to fattening at an early age with a moderate consumption of food, and with the smallest proportion of offal which has been with difficulty equalled, certainly has not been exceeded by the most skilful of his successors; and it is an arduous task, the utmost of labour and skill, that shepherds can perform who devote themselves entirely to the breeding of rams for the purpose of letting out on hire. This practice originated in Lincolnshire, where, in the early part of the last century, rams were let out from 10*l.* to 50*l.* each; but so great has been the improvement since that period, that they are now let out to common graziers at from 1 to 10 guineas and to breeders of rams at from 50*l.* to 500 guineas. The breeding rams are shown for hire at certain times and places during the summer where every one may select such as promise to maintain or improve the particular state of his flock, and at such prices as his means and experience may justify. Two or more individuals frequently join together in the hire of one ram, to which they put the best of their ewes, for the purpose of obtaining superior males for the future service of the rest of their flocks; and in particular cases when the owner of the ram does not choose to part with him, even for a season ewes are sent to him to be covered at a certain price per head superior animals of this class being very seldom sold altogether. Much as the mode of doing business has been represented as a monopoly and much as there sometimes may be of deception in making up rams for *shows*, all intelligent practical men must agree, that there can be no better method of recommending excellent breeders, and of spreading their improvements most widely, in the shortest period, and at the least possible expense. A single ram thus communicates its valuable properties to a number of flocks, often in distant parts of the country without distracting the attention of ordinary breeders from their other pursuits.

7148. The two methods of breeding common to all animals are also adopted in breeding sheep. Breeding from different families of the same race, commonly called *breeding in and in*, and breeding from different races, generally called *cross breeding*. Bakewell according to Sir J. Sebright (*On Improving the Breeds of domestic Animals*, &c.), effected his improvements by breeding from the same family; but according to Hunt, who has written an able answer to Sir J. Sebright's pamphlet (*A Letter &c. to Sir J. Sebright*, &c.), he bred from different relationships of the same family; it being out of his power to breed from different families of a race which he was at the time employed in farming, and cross breeding he did not approve of. Breeding *in and in* is so repugnant to human feeling that it is difficult to avoid considering it an unnatural practice for it does not follow that a flock of sheep in a wild state must necessarily breed in the nearest relationships, as father and daughter &c. on the contrary, it is more probable that remote relationships would be chosen to breed from, as they must necessarily be much more numerous. In a flock of sheep, or a herd of savage men, springing each from one pair every parent must necessarily have many more sons, and continue many times removed, than he can have mothers or daughters.

7149. Breeding from different families of the same race is the more general and approved practice. When a number of families of any breed have been for some time established in a variety of situations, and have had some slight shades of difference impressed upon them, by the influence of different soils and treatment, it is found advantageous to interchange the males, for the purpose of strengthening the coat, because, or remedying the defects of each family. Of this advantage Bakewell could not avail himself but it has been very generally attended to by his successors. Culley for many years, continued to hire his rams from Bakewell, at the very time that other breeders were paying a liberal price for the use of his own and the very same practice is followed by the most skilful breeders at present. In large concerns, two or more streams of blood may be kept distinct for several generations, and occasionally combined with the best effects, by a judicious breeder without having recourse to other flocks. (*See R. Soc. art. Agr. 177*)

7150. In breeding from one defined cross, the object is to acquire new properties or acquire defects. The method of doing this by cross breeding is attended with greater difficulties than in keeping from the same race. The very distinction of breeds implies a considerable difference among subjects in sexual property; and although the desirable property be obtained, it may be accompanied by such others as are by no means advantageous to a race, destined to occupy a situation which had excluded that property from one of its parents. To cross any mountain breed with Leicester rams, for example, with a view to obtain a propensity to fatten at an early age, would be attended with an enlargement of size, which the mountain pasture could not support, and the progeny would be a mongrel race, not suited to the pastures of either of the parent breeds. If the object be to obtain an enlargement of size, as well as a propensity to fatten, as in the case when Cheviot ewes are crossed with Leicester rams, the progeny will not prosper on the hilly pastures of their dams, and will be equally unprofitable on the better pastures of their sires. But the crossing of the cross succeeds well on these intermediate situations on the skirts of the Cheviot hills, where, though the summer pastures are not rich there is a portion of lowland for producing clover and turnips. (*Eng. Mag. Brit. art. Agr. &c.*)

7151. *In general rules in crossing breeds*, it is to be noticed that in every case where the enlargement of the carcass is the object, the cross breed must be better fed than its smaller parent. The size of the parents should also be but little disproportioned at first, and when some increase has been produced, one or more crosses afterwards may raise the breed to the required size. With these precautions, there is little reason to fear disappointment, provided both parents are well formed. (*General Report of Scotland, vol. ii. p. 16. 18.*)

7152. *The most advantageous and proper age for ewes taking the ram in the different breeds has not been fully shown*; but from a year to a year and a half old may be sufficient, according to the forwardness of the breed and the goodness of the lambs. Some judges of this by the production of brood or sheep a birth. It should not be done while too young in any case. Ewes commonly bring their first lamb when two years old in the hilly and mountainous districts of Scotland commonly not for a year after. Of course, they are usually eighteen or nineteen months old when they take the ram, throughout all the lowland districts.

7153. *In regard to the season of putting the rams to the ewes*, it must be directed by the period at which the fall of the lambs may be sent on desirable which must depend on the nature of the keep which the particular situation affords, but the most usual time is about the beginning of October, except in the Dorsetshire ewes, where the intention is suckling for house lamb, in which case it should be much earlier, in order that the lambs may be sufficiently forward. But, by being kept very well any of the breeds will take the ram at a much earlier period. Where the rams are young, the number of ewes should seldom exceed sixty for each ram, but in older rams a greater number may be admitted without inconvenience, as from one to two hundred, but letting them have too many should be cautiously avoided, as by such means the farmer may sustain great loss in the number of the lambs.

7154. *With respect to the period of gestation*, the ewe goes with lamb about the space of five months, consequently the most common lambing season is March, or the early part of April, but it has been observed that in many of the more southern districts, where sheep husbandry is carried on to a considerable extent, some parts of the ewe stock are put to the rams at much earlier periods so as to lamb a month or six weeks sooner, a practice which is attended with much profit and advantage in many situations where early grass-lamb is in great demand. It is usual for the rams to remain with the ewes for a month or six weeks, and in some cases longer in order to complete the business of impregnation which in some districts is ascertained by smearing the fore-bows of the rams with some coloring substance.

7155. *The practice of having a number of rams among the flocks* formerly adopted is highly exceptionable, as tending to prevent the main object and injure the rams. A better way is to let a h ram have a proper number of ewes, and with very choice stock to keep the ram in an enclosed small pasture, turning a few ewes to him, and as they are served replacing them with others. By this means there is more certainty, and more ewes may be impregnated. In such sort of fine stock, it is likewise of great utility to keep the rams during this season in a high manner. In this view a little oats in the straw or a mixture of barley and treacle, are excellent. Where ewes are backward in taking the ram, the best means to be employed are those of good stimulating keep. The rams should always be continued with the ewes a sufficient length of time.

7156. *The ewe will breed twice a year* if it be made a point to produce such an effect by attention and high keep, since she will receive the male indifferently at any season and, like the rabbit, very soon after bringing forth. Laid gives an instance of three of his ewes, well kept, lambing at Christmas, bringing off their lambs at Lady day, and producing lambs again the first week in June. It seems they stole the ram immediately after lambing, but brought the second time only single lambs, although of a breed that generally produces twins. There is no doubt but the sheep would produce young twice a year were the land practice resorted to, which has been so currently recommended with the rabbit, of allowing the male immediately after parturition. The ready way to render both the female and her progeny voracious. Could the lambs be advantageously weaned at two months, sufficient time would, he conceives, remain for the ewe to bring forth twice within the year. For example, suppose the young ewe tupped in August, the lamb would be dropped in the middle of January and might be weaned in mid March, the ewe again suckling the ram on the turn of the milk, like the sow, perhaps in or before April, she would then bring forth within the twelve months or in August. This plan would, continues Laid, at least injure the dams infinitely less than suckling during gestation.

7157. *When ewes are in lamb they should be kept in the pastures, and as free from disturbance as possible*, being carefully attended to in order to prevent accidents which are liable to take place at this time, such as those of their being cast in the furrows, &c. Where any of the ewes slip their lambs, it is advised by Stansfield that they should be immediately removed from the flock. They also require, under these circumstances, to be kept as well as the nature of the farm will admit, in order that there may be less loss at lambing time from the ewes being stronger and the lambs more healthy and better capable of contending with the state of the season at which they may be dropped. The shepherd should at this period be particularly careful and attentive to afford his assistance where it may be necessary. He should constantly have regard to the suckling of the lambs, and to see that the udders of the ewes are not diseased. His attendance will often be required in the night as well as the day. At this season covered sheep-folds are often of very great advantage in saving and protecting both ewes and their lambs.

7158. *In respect to the number of lambs at a birth* it is connected by Lardner with the fact that the ewe brings most commonly one, next in degree of frequency two, rarely from three to five lambs at a birth. This property of double birth is, he says, in some instances specific; the Down sheep usually yamling twins, and the large-headed Belge sheep, with their descendants our Teeswater, doing the same, and producing occasionally more at a birth. Other breeds bring twins in the proportion of one third of the flock, which is supposed to depend considerably on good keep. A certain number of ewes per centum prove barren annually. The cause very rarely natural defect. Sometimes over fatness a world state of body from poverty or neglect of the ewe, in other words, want of system in the shepherd.

7159. *The keep of sheep after lambing* where rich pastures or other kinds of grass lands cannot be reserved, should consist of turnips or other kind of green food provided for the purpose, and given them in a suitable manner. But where it can be done, it is always better to leave this sort of food untouched till about the period of lambing, when it should be regularly supplied in proportion to the necessity there may be for it. The ewe also should at this time much care to see that they are not upon a dry sheltered pasture, free from disturbance, and that neither they nor their lambs sustain injury from the too great

severity of the season. Whenever this is the case, they should be immediately removed into a proper degree of warmth and shelter till perfectly restored. It is likewise necessary, as well as useful practice, to lay lambs down, to take them and their lambs away from the common flock, putting them into a place of turnips or fresh dry pasture where there is shelter when necessary. In this manner much fewer lambs would be lost than would otherwise be the case. It is also found, that by a proper supply of turnips or other similar green food at this period, the work of the ewe is much facilitated, and the growth of the lambs greatly promoted, which is of much future importance as when they are started at the early period of their existence, they never turn out so well afterwards for the farmer. With the green and root crops and preserved after grass, hay, straw, corn, and oil-cake are in some cases made use of in the winter support of sheep stock. With turnips, where the soil is not sufficiently dry to admit the sheep, it is the practice to draw them and convey them to a good firm pasture, that the ewes may be landed upon them once or twice in the day as there may be occasion, care being taken that they are landed up clean, the circumstance of their being thus eaten may serve as a guide to the farmer for the supply that may be daily necessary. In this way this sort of food will be consumed with the greatest economy. Where the land is perfectly dry and the intention is to manure it for a grain crop, eating the turnips on the land, by means of portions hurled off as wasted, is a good practice. With this sort of food, especially where it produces swelling in the ewes green frozen hay cut straw or pease hanks should certainly be given, and also with rape, &c.

7160 The castrating lambs may be performed any time from the age of a fortnight or three weeks to that of a month or six weeks, and in some districts it is deferred to a considerably later period. It is, however, the safest method to have it executed early as there is less danger of too much inflammation taking place. But in all cases the lambs should be in a healthy state when it is done, as under any other circumstances they are liable to be destroyed by it. The operation is usually performed by the shepherd, by opening the scrotum or cod and drawing out the testicles with the spermatic cord. This he often does with his teeth in the young state of the animal but where the operation is performed at a later period it is usual to have recourse to the knife, the arteries being taken up and secured by means of ligatures, or the sewing iron. The business, if possible should be done in fine weather, when not too warm and the castrated lambs be kept in a dry, sheltered, quiet situation for a few days, until the inflammation is gone off. If it should happen to be wet at the time, it may be advisable to have them under some sort of shelter where they can have room to move freely about.

7161 The weaning of lambs should be effected when they are three or four months old, as about July but it is done more early in some districts than in others. A proper reserve of some fresh pasture grass, where there may be a good time for the lambs to feed upon should be had recourse to, as it is of much consequence that an ample provision of this sort be had in order that the growth of this young stock may not suffer any check on being taken from the mother. Where they have been continued so long as to graze with the dams, little check will be sustained in their separation if turned upon such good feed. Some advise clover in blossom as the most forcing sort of food in this intention and with other sanctified rumen is highly valued for the same purpose. When good feed is not provided of some of these kinds, the lambs soon decline in flesh, or in the technical language of the flock are said to pinch, and when once this happens they never afterwards thrive so well, however good the management may be. With regard to the ewes, they should be removed to such distant pastures or other places as that they may not be heard by the lambs, which would cause them to be disturbed in their feeding and where the ewes sustain any inconvenience from their milk, as by their udders swelling, it should be drawn once or twice, as by this means bad consequences may be prevented, and as soon as the lambs have been removed the ewes are returned upon the pastures destined for their summer support. There is, however, one caution to be attended to in first turning the lambs upon rich keep, which is that of letting them be in some degree satisfied with food previously that they may not be surfeited by too quick and full feeding and hence or less as it is termed keeping them gently moving about the field has also been advised in this intention. In some places, where the lands are of the more poor kind, it is a custom to send the lambs to the more rich vale or marsh districts, to be brought forward in condition or fattened. In those cases where the lands of the male kind are reared on the home lands as wethers, they are usually returned to the flock in the latter end of the year but which is not by any means a good practice, as they often suffer for want of proper keep in the winter and lose what they had previously gained in growth and condition. A practice the reverse of this has long been in use among the store-masters of Scotland. They send their lambs, as soon as weaned, to some rough coarse pasture, often at a distance of several miles, where they remain for six or eight weeks. The opinion is that this renders them more hardy. Some grounds are occupied chiefly for this purpose, being kept for summering lambs, as it is called, the owner of the lamb paying a penny or three halfpence a week for each. The practice, it is believed is not now so common as it has been.

#### SECT. IV Rearing and general Management of Sheep.

7162. In the practice of sheep husbandry different systems as we had recourse to, according to the extent and nature of the farms on which they are kept, and the methods of farming that are adopted on them, but under all circumstances the best sheep-masters constantly endeavour to preserve them in as good condition as possible at all seasons.

7163 With the pasture lands of sheep this is particularly the case and with the view of accomplishing it in the most complete manner it is useful to divide them into different parcels or lots in respect to their ages and sorts, as by that practice they may be kept with greater convenience and benefit than in large flocks together under a mixture of different kinds as in this way there is not only less waste of food, but the animals thrive better, and the pastures are fed with much more ease. The advantage of this management has been fully experienced in many of the northern districts, where they usually divide the sheep stock into lambs, yearlings, wethers, and breeding ewes and in this method it appears not improbable that a much larger proportion of stock may be kept, and the sheep be preserved in a more healthy condition. With a breeding stock the sheep-master must act according to his circumstances, situation, and capital, which he possesses either selling the lambs to go to keep, fattening them for grass lamb, sending them for home lamb, or keeping them on to be grazed and sold as store or fat wethers the ewes being sold less or in store condition, or fattened, as circumstances, profit, and convenience may point out.

7164 Another practice but which requires much capital as well as knowledge, experience, and attention, is that of breeding and fattening off all lambs, both wethers and ewes, especially where markets for their sale when fat are conveniently situated or this system may be partially acted upon, varying the plan according to capital, circumstances, and the nature of the times. In such case, whenever some stock becomes extravagantly high it is mostly a good way to sell.

7165 The sheep farming of the arable or low warm districts of the kingdom consequently differs in various particulars from that of the hilly and mountainous districts; we shall, therefore, first give a general view of the sheep management of arable lands, and next of mountainous districts.

**Section I. Rearing and Management of Sheep on rich grass and fertile Lands.**

7166. The most general sheep husbandry on rich lands, or where tannage and other green food is raised for winter consumption, is to combine the breeding and feeding branches, leading to each according to the returns of profit.

7167. A method very common among arable farmers, and which is attended with the least trouble and hazard, is that of purchasing a store flock, as lambs, wethers, and what are termed cronies, or old ewes some of the last sort often proving with lamb, may be fattened off with them to good account. It is likewise often the case that ewes are disposed of in lamb, or with lambs by their sides, in what are termed couples, in which circumstances it is frequently a good practice to make annual purchases of them, in order to the fattening of both, and selling them in that state within the year. In the purchasing of sheep, which is often done from very distant fairs and markets, much care and circumspection is necessary whenever the sort or condition with which they are bought may be. In these cases much advantage, especially when at a considerable distance, may be derived by employing a salesman on the spot.

7168. The treatment of the lambs is the first consideration in the mixed sheep husbandry.

7169. Lambs are either suckled or fattened on grass, or sold in autumn as lean stock. With regard to those that have been suckled or fattened in the house, much attention is required to have them early to their bang well, regularly, and very cleanly kept and suckled, as well as to the ewes being of the right sort, and the best milkers that can be provided, and to their being fully supplied with food of the most nourishing and succulent kind. Their tails and udders should have the wool well clipped away from them in order that they may be preserved in a perfectly clean state. The lambs also require especially towards the close of their fattening, to have regular supplies of barley wheat, and pea meal, ground together in combination with fine green vetch hay. When these have been sold off the lambs which have been fattened on the green grass land will be in the best condition at the markets, in the spring and summer months, and these will be followed by the sale of the store lambs, at the different autumnal fairs.

7170. The selection or setting of the lamb-stock is the first business of sheep management after the lambs have been weaned.

7171. It is generally performed in the month of July or August, at which period the furs for the sale of lambs mostly take place. And as at this time the whole are collected together for drawing into different lots, it is a very suitable period for selecting or choosing those that are to supply such deficiencies in the breeding flocks. In his *Calendar of Husbandry*, Young has remarked, that in making this selection the farmer or his shepherd usually (whatever the breed may be) rejects all that manifest any departure from certain signs of the true breed: thus, in a Norfolk flock, a white leg, and a face not of a hue sufficiently dark, would be excluded, however well formed. In the same manner a white face on the South Down or Wiltshire, a black face would be an exclusion, or a horn that does not fall back. In Dorsetshire a horn that does not project, &c.

7172. The selection of the grown stock generally takes place after the lambs are weaned, or, at all events, before tupping season, though wethers may be drawn out of the flock at any time. A certain number of old ewes or cronies are removed every year and these as well as the wethers are fed off for the butcher, either on grass, artificial herbage, or roots, according to the situation and circumstances of the farm, and season of the year.

7173. The shearing of sheep is an annual operation, which includes several preparatory measures and after-processes. These are, washing, separation, catching, clipping, marking, and tail-cutting.

7174. The proper time for clipping or shearing sheep must be directed by the state of the weather and the climate in the particular district, as by this means the danger of injury by cold from depriving the sheep of their coats at too early a season, and from heat by permitting them to continue on them too long, may be avoided in the best manner. But another circumstance that should likewise be attended to in this business is that of the wool being fully grown or at the state of maturity as where the clipping precedes that period, it is said in the *Annals of Agriculture* to be weak and scarcely capable of being spun, and if protracted later, it is yellow, felted and of an imperfect nature. It has been stated that for the more warm sheltered districts in the southern parts of the kingdom the beginning or middle of June, when the weather is fine, may be in general the most proper. But in the more exposed districts in the northern parts of the island, the middle or latter end of the same month may be more suitable provided the season be favourable. But with the fattening sheep in the enclosures it will mostly be necessary to perform the work at an earlier period in every situation, as the great increase of heat from the setting in of the summer weather added to the warmth of the house, becomes very oppressive and injurious to them in their feeding. There never can be any difficulty in ascertaining the proper time for shearing, because the separation of the old wool from the new is always distinctly marked in a thriving sheep and this happens earlier or later according to the age and condition of the animal. Hence, from the beginning of May or earlier, till the first week of July shearing goes on in different districts beginning with the *Welsh* wethers, and ending with the small warring ewes of the Highland districts. From the middle of May to the middle of June is the busiest period.

7175. Sheep-shearing in *Essex* March commences about midsummer and finishes about the middle of July. Those who shear first think they escape the effects of the fly, and those that shear late apprehend they gain half a pound weight in every fleece, by the increased perspiration of the sheep. In early shearing, the wool has not the condition which it afterwards acquires, but the hot weather causes a good deal of trouble in detecting the fly. The lambs that are sold in Smithfield market are, we believe, seldom or ever shorn. All over the north of England, and throughout Scotland, lambs are never shorn. They lose their first fleece when about fifteen months old.

7176. Clipping off the coarse soiled wool about the thighs and docks, some weeks before the usual time of washing and clipping the sheep, is an excellent practice, as by this means the sheep are kept clean and cool when the season is hot, and with ewes the udders are prevented from becoming sore.

7177. In preparing for the purpose of washing, the flock is brought to the side of the washing-pool, and there lambs and sheep of different kinds, fit to be washed, are put into separate folds; and such lambs as are too young to be clipped are not washed, but confined in a fold or enclosure of any kind, at such a distance from the washing place as that they may not disturb their mothers by their bleating. The object of washing is simply

to free the skins from dust and dirt of various kinds. In Devonshire and Spain, the short-woolled sheep are not washed.

7176 In performing the operation of washing, it was formerly the method, and it still exists in the north, to have the washers standing up to the breast in the water; but from the inconvenience and danger of it, the men requiring a large supply of spirituous liquors, and being liable to be attacked with cold, rheumatism, and other diseases, as well as being apt to despatch the work with too much expedition, or as to leave the wool insufficiently clean, it has been proposed by Young, in his *October* to rail off a portion of the water in a stream or pond (fig. 391) for the sheep to walk into by a sloping mouth at one end (a),

and to walk out by another at the other end (d) with a depth sufficient at one part for them to swim and to pave the whole breadth need not be more than six or seven feet. At one spot on each side of this passage where the depth is just sufficient for the water to flow over the sheep's back a oak or box (e), water tight, should be fixed for a man to stand in dry the sheep being in the water between them, they wash in perfection and pushing them on, they swim through the deep part, and walk out at the other mouth, where a clean pen (f) or a very clean dry pasture, is ready to receive them of course there is a bridge railway to the tubs, and a pen at the first mouth of the water (e) whence the sheep are turned into it, where they may be soaking for a few minutes before being driven to the washers. But other more cheap contrivances may be provided, where there is clean water at hand for the purpose.

7176 After sheep are washed, they should on no account be driven on dry or dusty roads but should have a clean hard pasture for a few days, until they are perfectly dry and in a proper condition to be shorn.

7180 The common method of catching the sheep, in order to lay it on it on its back to be shorn, is by the hinder leg, drawing the animal backward with a crook (fig. 392. a, b, c)

to the adjacent shearing place the hand holding the leg to be kept low when at the place it is turned on its back; or they are moved bodily or one hand placed on the neck and another behind, and in that manner walked along the first or common mode he thinks the most safe. Sheep fed on rich pastures, and fleshy if handled hard and bruised, the parts are liable to fatal morifications an accident which often happens, on which accounts pens upon some lands are obliged to be lined with woollen, or many would die from bruises.

7181 In performing the operation of shearing, the left side of the sheep is placed against the shearer's left leg his left foot at the root of the sheep's tail, and his left knee at the sheep's left shoulder

7182 The process commences with the shears at the crown of the sheep's head, with a straight cut along to the loins returning to the shoulder, and making a circular shear around the off side to the middle of the belly the off hinder leg next then the left hand holding the tail, a circular shear of the rump to the near back of the sheep's hind leg the two fore feet are next taken in the left hand, the sheep raised, and the shears set in at the breast, when the remaining part of the belly is sheared round to the near side; lastly the operator kneeling down on his right knee, and the sheep's neck being laid over his left thigh he shears along the remaining side.

7183 The method in Northumberland, introduced by the Manx Colley is to begin at the back part of the head, in order to give room for the shears to make their way down the right side of the neck, to the middle of the breast. The man then sits down upon his right knee, laying the head of the sheep over his left knee bent, and beginning at the breast, clips the underneath of the neck, then takes off the back of the neck, and all the way down below the

throat upwards to the left cheek. He then changes to the contrary side, and makes his way down to the open of the right flank. This done he returns to the breast, and takes off the belly after which it matters not which side he clips, because being able to clip with either hand, he makes his shear points exactly at the middle of the back, all the way until he arrives at the thighs or legs. He then places the sheep on its left side, and putting his right foot over the neck, and the other forward to the undermost hind leg, clips the right side, then turning the sheep over finishes the whole.

7184 The fleece being removed, is wound up that is, deprived of any clotted wool or dirty part, and leaped with the short side outwards, beginning at the breast and ending at the shoulder, where the neck wool serves as a handle.

7184. *Marking* is performed on each sheep about a week after the fleece is removed. The object is to identify the individuals as the property of the master. Sometimes initials are impressed, and at other times other marks. They are impressed by stamps, or merely chalked or painted on. A stamp dipped in warm tar is the most durable mode. Some place the mark on different parts of the sheep, according to its age; others cut the mangle of the ears in different ways.

7185. *Shortening the tails of the sheep* is performed in almost all the sheep districts of the kingdom except in Dorsetshire, which seems to be a useful practice, especially with long-woolled sheep, in keeping the animals more clean behind, and of course less liable to be stricken with the fly.

7187. *It has, however, been suggested* in the ninth volume of *Annals of Agriculture*, that by this custom the sheep may be rendered less able to drive away the flies. The general prevalence of the practice would, however, seem to prove its being of advantage. There is much difference in the manner of performing the business in different districts in respect to the length but four or five inches being left is quite sufficient. It is usually done while the animals are young. In all sheep pastures the hedges should be well cleared from brambles, as their coats are often injured by being torn by them. And all sorts of poisonous reptiles should be as much as possible destroyed, and removed from such land.

7188. *The mode of pasturing sheep, or of feeding them on herbage or roots* having been described when treating of these crops, the more general practices of rearing and management of lowland sheep husbandry may be considered as developed. Some peculiar practices and the mode of fattening lambs will be found in subsequent sections.

7189. *The practice of giving salt to sheep* deserves to be generally recommended. It is given in small lumps brought every day throughout the year and in rainy weather twice a day or under cover that it may not be washed away. The practice is particularly recommended, when sheep are first put to lambs, as to the quantity for each sheep, it is said that any quantity may be laid before them, and that no danger but the reverse, will result from their having at all times as much as they will voluntarily take.

## SECTION 2. Rearing and general Management of Sheep on Hilly and Mountainous Districts, or what is generally termed Store Sheep Husbandry

7190. *The best store farmers in Britain* are unquestionably those on the Cheviot hills, which border the two kingdoms and an account of their management may be considered as applicable to the mountainous districts of the whole kingdom. It is, indeed, applied by the migrations of the Cheviot and Teviotdale farmers, both in the North Highlands, on the Sutherland estate and in Wales. No regular system of store farming, as observed by Napier (*Treatise on Store Farming*) appeared previously to his own and accordingly from this work, and an excellent account published in the *Supplement to the Encyclopædia Britannica*, we have extracted what follows.

7191. *A general idea of the extent and nature of a store farm* may be obtained by referring to that of Thirlstair in Kintyre forest, a plan of which (fig. 83.) is given by Captain Napier. It contains one thousand six hundred and fifty-one acres; of which one thousand four hundred and sixty-four acres are in open hill pasture, seventy in plantation forty in arable and meadow about sixty in six enclosures, and the rest in shepherds' and other cottagers' houses, with their allowance of ground for a garden and cow. What distinguishes this farm from most others is the number of rills, or small circular enclosures (O) for sheltering and feeding sheep during storms of snow, which are distributed over it being no fewer than thirty-seven. The advantages of these stalls in districts where sheep are liable to be harried by snow Captain Napier considers very great, and to promote their more general introduction seems to have been one principal inducement for publishing his book. We shall recur to the subject in the following section, when treating of crotching, folding, housing, &c. In the mean time, we are informed that Captain Napier's round stalls are not generally approved of, but that one is preferred which has four concave sides. See *Fairbairn's Treatise on Store Farming*, Edin. 8vo. 1825.

7192. *In the practice of store farming* the rams are put to the ewes for the purpose of copulation in November, a little earlier or later according to the prospect of spring food, but seldom before the eighth or tenth of that month. The number of rams required is more or less, according to the extent of the pasture, and their own age and condition. If the ewes are not spread over an extensive tract, one ram to sixty ewes is generally sufficient. It is usually thought advisable to separate the gimmers (sheep once shorn) from the older ewes, and to send the rams to the latter eight or ten days before they are admitted to the former. Notwithstanding this precaution, which retards their lambing season till the spring is further advanced, ewes which bring their first lamb when two years old, the common period on the best hill farms, are often very bad nurses, and in a late spring lose a great many of their lambs, unless they are put into good condition with turnip before lambing, and get early grass afterwards. This separation and difference in the time of admitting the rams to the ewes and gimmers, should therefore be always attended to. When a farm under this description of stock has the convenience of a few good enclosures as in Thirlstair's farm for example, still more minute attention is paid by skilful managers. It is not sufficient that the rams are carefully selected; they perhaps double the number the ewes also are drawn out and sorted, and such a ram appropriated to each lot as possesses the properties in form or fleece in which the ewes are deficient. In other cases, the best ram and the best lot of ewes are put together. When neither of these arrangements can be adopted, owing to the want of enclosures it is the practice to send the best rams to the ewes for a few days at first, and those of an inferior description afterwards. In every case, when the farmer employs rams of his own stock, he is careful to have a few of the best ewes covered by a well-furrowed and then-crotched ram for the purpose of obtaining a number of good ram-lambs, for preservation or improving the character of his stock.

7193. *The flock through winter* in a store-breeding farm, consists of ewes and gimmers, which should have lambs in spring; ewe lambs or hags; and a few young and old rams. All these are sometimes allowed to pasture promiscuously; but on the farms around Cheviot the ewes and ewe hags are kept separate, and the ewe hags are either put on rough pastures, which have been lightly stocked in the latter end of summer, or put a few hundred once a day in addition to the remaining of their summer pasture. The most essential preventive of the devastating dangers to which sheep of this age are liable is turnips; and though they should never taste them afterwards, a small quantity is frequently given them during their first winter. After the rams have been separated from the ewes, they are usually indulged with the same feeding as the hags.

"184. The ewes, during winter are seldom allowed any other food than what their summer produce affords, except that a small part of it may sometimes be cut lightly moist, and reserved as a reserve  
293

against severe storms. When these occur however as they often do in the Cheviot district, there is little dependence on any other food than hay. When the snow is so deep as completely to cover the herbage, about two stones *avoids* of hay are allowed to a score of sheep daily and it is laid down, morning and evening, in small parcels on any sheltered spot near the house, or under the shelter of stails or clumps of trees, on different parts of the farm.

"195. The ewes in March, at least the gunners or young ewes, are commonly allowed a few turnips once a day on farms on which there is any extent of arable land which are either carted to their pastures, or sown on the ground, by bringing the sheep to the turnip field through the wighs. A part of the field, in the latter case is cut off by rails, or by hurdles which enclose the sheep in the same way as if they were intended for fattening. When they are ready to drop their lambs, they are no longer kept on the turnip field, and get what turnips may be left on their pastures. But it is seldom that the turnips last so long, though it is desirable to have a few remaining to be given to the weakest ewes, or to such as have twins in a separate enclosure.

"196. A few days before the time of lambing, the ewes are collected for the purpose of being addled. The sheep are raised upon their buttocks, their backs next to the operator who then bends forward and plucks off the locks of wool growing on or near the udder, for the purpose of giving free access to the expected lamb. At the same time he ascertains the condition of the ewe, and marks such as do not appear to be in lamb, which may then be separated from the others. This operation is not without danger and several premature births are usually the consequence. It is therefore not so general a practice as it was formerly though still a common one on many if not on most farms.

"197. The separation of the hags from the ewes where these have been allowed to pasture promiscuously, should always take place at the commencement of the lambing season, and the lowest and finest part of the pasture be exclusively appropriated to the nursing ewes. On the Cheviot hills the hags are generally pastured apart on the coarser herbage.

"198. The lambing season commences with the first or second week of April, according to the time at which the rains were admitted and such as have twins, generally lamb among the first of the flock. At this season the most constant attention is indispensable on the part of the shepherds, both to the ewes in labour and to the newly dropped lambs. Though the Cheviot ewes are not so liable to labour in particular as some larger breeds which are in higher condition, and though they make good nurses, unless they are very lean and their food scanty yet, among a large flock, there are always a number that need assistance in lambing, and in a late spring not a few who have not milk sufficient for their lambs, particularly among the gunners or young ewes. A careful shepherd at this time always carries a bottle of milk along with him, which he drops from his own mouth into that of the lamb that may need it, brings the ewes that have little milk to a better pasture, or to turnips, and sometimes such as have mistaken their lambs in a small pen, or paddock as it is called, temporarily encloses in some part of the farm-enclosure. The same confinement is necessary when it is wished to make a ewe that has lost her very lamb, nurse that of another ewe that has had twins, or that has perished in lambing, or is from any other cause incapable of rearing her lamb. The ewe, after being shut up a few hours with the strange lamb, usually adopts it to the teat, and ever after treats it as her own though sometimes a little deception is necessary, such as covering the stranger with the skin of her own lamb. At this important season, an enclosure of rich early grass, near the shepherd's cottage, is of vast advantage. Whether he carries the ewes and twins,

such as have little milk; those that have been induced to adopt another's offspring; and, generally, all that need to be frequently inspected, and are in want of better treatment than the rest of the flock. (*Supp. &c.* 176.)

779. *Castration* is performed in the male lambs when a few days old, the ewe lambs are never castrated, and weather is chosen and the operation performed in a fold on small quantities at a time.

780. *The late leaving ewes* are separated from the ewes and lambs at the end of the lambing season, and kept by themselves, that they may be more under the eye of the shepherd, than if scattered over all the pasture. It is desirable to allow them fine grass for a few weeks after lambing, that their lambs may come to be nearly equal to the rest of the flock when weaned, or if they are too late for this, that they may get ready for the butcher by the month of August, beyond which period the ewes must be much injured by sucking them. (*Supp. &c.* art. 4, r. 174.)

781. *Washing* in store-farming, is performed when the wool has risen sufficiently, which is easily known by the appearance of a new growth. The barren sheep are first brought to the washing pool. Sometimes they are hand-washed by men who stand in the pool, and have the sheep forced towards them singly, but more commonly the Cheviot sheep, especially if the flock be numerous, are compelled to leap into the pool in a body for three or four times successively, and it is desirable that they should have room to swim a little, and come out on a green low bank on the opposite side. After being washed the sheep are preserved as far as possible from rubbing against earthen dykes or banks, and from lying down on any dirty spot which might soil their wool. (*Supp. &c.*)

782. *Marking* in general sheep-farming (785), takes place before the shorn sheep are turned out to pasture: they are marked, commonly with the ear, by a stamp or knot in a given language, dipped in tar heated to a thin fluid state, and it is not unusual to place this mark on different parts of the body according to the sheep's age.

783. *The weaning of lambs* takes place when they are about three months old, sometimes sooner. When the ewes are gathered to be washed or shorn, the ewe lambs to be kept for supplying the place of the old ewes are sold, or are stamped in the same way as the ewes. The store lambs are sent to some clean grassy pasture for a few weeks, and where the farm does not afford this accommodation, they must be removed, as it is called, at a distance. Several farms near Cheviot, and on the Lammernuir hills in Berwickshire, are appropriated to this purpose, the owner of the lambs paying so much a head for six or eight weeks. In the mean time the ewe hogs, or gimmers, as they are denominated after shearing have joined the ewe stock, and the lambs, when brought home, go to the pasture which they had occupied. Wherever they may be kept in winter it is always desirable to allow them a few turnips, along with a full tub of coarse barley.

784. *The practice of suckling ewes* after the separation of the lambs is still continued in a few places. This very objectionable management is generally continued for six or eight weeks. The value of the milk of such ewe for this time may not exceed from one shilling to one shilling and sixpence a head, and the sheep are injured to at least three times that amount, independent of accident, in the milking fold. The cream is separated from the ewe milk, and made into butter for smearing, and the milk (mixed with cow milk, and converted into cheese. The most skilful store-masters however have either laid aside milking, unless for a few days, or have shortened the period to two or three weeks.

785. *The selection of the ewes or old ewes to be sold* generally takes place in September or October when they are sold to the feeder and replaced by lambs of the current year. On the lower hills ewes are generally disposed of after having lambed three seasons, or under four and a half years of age. In some situations they are kept on till a year older, but when they are purchased, as they usually are, to be kept another year on lower grounds it is commonly for the interest of the store-farmer to sell them when still in their full vigour. Skilful managers do not content themselves with drafting them merely as, owing to age, for as there is no disadvantage in keeping a few of the best another year, they take this opportunity of getting rid of such of the flock of other ages as are not of good shape, or are otherwise objectionable. As soon as the ewes to be disposed of are drafted from the flock they are kept by themselves on better pasture, if the circumstances of the farm will admit of it. Sometimes they are carried on till they are fatigued, and turnips are often purchased for them at a distance. When this is the case, it is not thought advisable to keep them longer than till between Christmas and Candlemas, as an old ewe does not improve like a wether in the spring months. (*Supp. &c.*)

786. *The salting or smearing of sheep* is an operation scarcely known in England, and not practised by the Welsh; some store farmers in the midland districts of the northern counties consider it unnecessary, but in all very cold situations it is still employed. The object of this operation is to destroy vermin to prevent cutaneous diseases, and to promote the warmth and comfort of the animal during the rigors of the coming winter. It is not necessary with sheep kept on low grounds, and well fed during winter, and it may occasionally be omitted for one season, particularly with old sheep, without material injury, but notwithstanding the ridicule that speculative writers have attempted to throw upon the practice, it is almost universally considered necessary and beneficial on high exposed situations, by the store-farmers of the border hills. Smeared wool does not sell so high as white wool, but the greater weight of the former more than compensates for the difference in price. *General Report of Scotland* vol. (ii.) The season of salting or smearing is usually towards the end of October or beginning of November, before the rains are sent to the ewes. The most common materials are butter and tar mixed in different proportions, a greater proportion of tar being employed for the hogs or young sheep than for the older ones. The proportions are also different on almost every farm, and more tar is thought to be necessary, according to their greater elevation and exposure. In Roxburghshire, some mix two gallons of tar with thirty six pounds of butter as a sufficient allowance for three score of sheep, but for the same number it is more common to allot only one stone (twenty four pounds) of butter to two gallons of tar. (*Edinburgh Review* p. 15.) A common proportion of late has been about fourteen pounds of butter to two Scotch pints of tar (nearly 14 quarts English wine measure) for ewes, and eleven pounds to the same quantity of tar for hogs. This mixture should consist from twenty to twenty five of each, which is the number one man can do in a day. The expenses, according to present prices, will be about nine pence for each sheep, other articles such as oil, palm-grease, tallow &c., have been recommended in place of butter, but none of them are in general use, and the only addition that is approved of is a little butter milk. The butter is slowly melted and poured upon the tar, and the mixture is constantly stirred till it becomes cool enough for use. The wool is accurately parted into rows from the head to the tail of the animal, and the salve is carefully worked upon the skin with the point of the finger at the bottom of each row. (*Supp. En. Brit. art. Agr. 180*) The practice of salting has undergone a change within these four years, and is not so general now as formerly, the low price of smeared wool having forced the store-masters to try other ingredients than tar. In the *Farmer's Magazine*, vol. xiv. are some notices of these experiments on smearing; which have not, however, been so long in use as to afford certain results. The object at present is as far as possible to dispense with tar, by which the wool is rendered unfit for certain sorts of manufacture.

787. *The care of sheep during storms* is a business requiring constant attention. In storms of wind and rain, or what are called *flood storms* by the shepherds, the sheep will, in a great measure, take care of themselves, by pasturing in situations naturally sheltered. All that is required is to remove any of the more delicate into a covered fold or sheep-house, though such conveniences are seldom to be found on mountain farms. But in a storm of snow the natural shelter to which the sheep have recourse becomes the great repository of drift, and the herbage all beneath it. It is in such a situation that the shepherd is obliged to place the stalls, or circular folds (*Ag. 483 C.*) into which the sheep should be driven, or will naturally enter on the commencement of the storm. The round form for these stalls or folds is decidedly preferable to any figure with straight lines, as these invariably favour drift. Where no

artificial shelter is provided (sometimes houses sometimes take place on mountain farms. The sheep are

buried many feet deep in the snow, and though the shepherd, with such assistance as he can procure, armed with poles and spears, and aided by the agency of his dog, may dig out a few, yet the greater number perish. While the sheep remain in artificial shelters of any kind they must, of course be fed, and the only convenient food in such cases is hay straw or dried spury (the latter seldom resorted to in this country), which should be put into baskets, or racks (fig. 894.) The Ryeland breed of sheep in Herefordshire, and some of the flocks in the Highlands of Scotland, are put under cover nightly throughout the year a practice which has probably originated in security and been continued as matter of convenience and habit.

### SECT. V. Folding of Sheep.

7206. *Cotting or folding* is a practice more or less extensively followed with particular breeds and in particular districts, but now generally on the decline

7207. *It was formerly thought to be indispensably necessary* to the success of the farmer in different districts but of late a different opinion has prevailed, except in particular cases, and it is considered as merely enclosing one field at the expense of another. The practice may however be beneficial where there are downs, heaths, or commons. Folding has been chiefly confined to England, and a small part of Wales and Ireland. The object is to enrich the arable land but as this is done at the expense of the pasture, it is truly, as Bakerwell expressed it, "robbing Peter to pay Paul."

7210. *The sheep best adapted to the fold* are those of the more active, short-wooled varieties, such as the Norfolk, Wiltshire, and South Down breeds the heavy long woolled kinds being less hardy, and some of them, as the Leicester, much too valuable for a mode of treatment that converts them into dung carriers. The following calculation by Marshall will show that though in open lands, the practice may be in some cases tolerated on the ground of convenience or expediency it can possess no recommendation as a profitable mode of management in other circumstances.

7211. *The morning* (September 23 1780) measured a sheep fold, set out for six hundred sheep, consisting of ewes, wethers, and grown lambs. It measured eight by five and a half rods, which is somewhat more than seven rods to one hundred, or two yards to a sheep.

7212. *August 23. 1781* Last autumn made an accurate experiment, on a large scale, with different manures for wheat, on a sandy loam summer followed. Part of an eighteen acre piece was manured with fifteen or sixteen loads of tolerably good farm-yard dung an acre part with three chaldrons of lime an acre the rest folded upon with sheep twice the first time at the rate of six hundred sheep to a quarter of an acre (as in next minute) the second time thinner In winter and spring, the dung kept the land and now at harvest, it has produced the greatest burden of straw The sheep-fold kept a steady pace from seed-time to harvest, and is now evidently the best corned, and the cleanest crop. The lime, in winter and spring, made a poor appearance but after some showers in summer it flourished much, and is now a splendid crop, not less, I apprehend, than three quarters of an acre.

7213. *From these data* the value of a sheep-fold, in this case may be calculated. It appears from the first minute, that one hundred sheep manured seven square rods daily. But the second fold was thinner supposes nine rods, this is, on a par of the two foldings, eight rods a day each folding. The dung could not be worth less than half a crown a load, and the carriage and spreading ten shillings an acre together fifty shillings an acre which quantity of land the hundred sheep teached twice in forty days. Supposing there to be folded the year round they would, at this rate, fold nine acres annually which at fifty shillings an acre, is twenty two pounds ten shillings a hundred, or four shillings and sixpence a head. In some parts of the island, the same quantity of dung would be worth five pounds an acre, which would raise the value of the teath to nine shillings a head which at two-pence a head a week, is more than the whole year's keep of the sheep. It does not follow however that all lands would have received equal benefit with the present consideration which, perhaps, had not been folded upon for many years, perhaps never before, and sheep folds, like other manures, may become less efficacious the longer it is used on a given piece of land. (Marshall's Rural Economy of Norfolk, vol. ii. p. 23.)

7214. *To fold on it and be tillage all the year* is nearly impracticable and where it could be done the manure would be greatly diminished in value from rain and snow to say nothing of the injury to the sheep themselves. So that the estimate of four shillings and sixpence or nine shillings a head, is evidently in the extreme.

7215. *According to Arthur Young (Farmer's Calendar)* the same land will maintain one fourth more stock when the animals are allowed to depasture at liberty than when confined during the night in folds. The injury to the stock themselves, though it is not easy to mention its precise amount with any degree of accuracy cannot well be doubted, at least in the case of the larger and less active breeds, when it is considered that they are driven twice a day sometimes for a distance of two, or even three miles, and that their hours of feeding and rest are in a great measure controlled by the shepherd and his boy. When they are kept in numerous parcels, it is not only driving to and from the fold that exhausts them, but they are at that driving about in a sort of march all day long when the strongest have too great an advantage and the flock divides into the head and tail of it, by which means one part of them must trample the food to be eaten by another. All this points the very reverse of their remaining perfectly quiet in small parcels.

7216. *The result of Parkinson's experiment* is, "that were the pasture sheep of Lincolnshire to be got into a fold once a week, and only caught one by one, and put out again immediately it would prevent their becoming fat." (Parkinson on Live Stock, vol. i. p. 367.) The only sort of folding ever adopted to any extent by the best breeders is on turnips, clovers, fens, and other rich food, where the sheep feed at their ease, and manure the land at the same time.

7217. *Folding in winter* is described by Dickson (Complete Farmer art. Sheep) as combining all the advantages of folding on arable lands without any of its disadvantages. By this practice the sheep are confined at night in a yard wall and regularly filled with straw, stubble or turn by which means the flock is said to be kept warm and healthy in bad seasons, and at the same time a surprising quantity of manure accumulated. A great improvement on this method it is said, would be, giving the sheep all their food (except their pasture) in each yard, viz. hay and turnips for which purposes they may be brought up not only at night, but also at noon, to be baited but if their pasture be at a distance, they should then, instead of baiting at noon, come to the yard earlier in the evening, and go out later in the morning. This is a practice, he says, that cannot be too much recommended for so warm a lodging is a great matter to young lambs and will tend much to forward their growth the sheep will also be kept in good health and what is a point of consequence to all farms, the quantity of dung raised will be very great. If this method is pursued through the month of December, January, February, March, and April, with plenty of other one hundred sheep will make a dunghill of at least sixty loads of excellent stuff, which will amply manure two acres of land whereas one hundred sheep folded (supposing the grass dry enough) will not, in that time, equally manure an acre.

7213. *The subject of this sort of fattening, is warmly recommended by Mr. J. Smith and A. Young, in the husbandry of Scotland, coinciding with that of a very superior judge, who says, "that such a method may be advantageous in particular cases, it would be rash to deny; but generally it is not advisable, either on account of the sheep, or any alleged advantage from the manure they make. As to the sheep, this driving and beating, especially in winter, would be just as hurtful as folding them in the common way; and it has been found that their wool was much injured by the broken litter mixing with the fleece in a manner not to be easily separated; besides, now that it is the great object of every skillful breeder to accelerate the maturity of his sheep, as well as other live stock, among other means, by leaving them to feed at their ease, and if circumstances permit, in small parcels; such a practice as this can never be advisable in their management, and with regard to manure, there can be no difficulty in converting into it any quantity of dung, stable, and farm, by cutting the in fold-yards, or green herbage in summer and spring, or other sown land, in winter; while the soil, especially if it be of a light porous quality, is greatly benefited both by the dung and treading of sheep, allowed to consume the remainder of both sorts of food on the ground. It is true, that the dung of sheep has been generally supposed to be more valuable than that of cattle, but accurate experiments have not been made to determine the difference in this respect, among these and other polygastrie animals. The greater improvement of pastures by sheep is probably owing as much to their mode of feeding, as to the richer quality of their dung."* (*Sup. & Brit. art. Agr.*)

#### SECT. VI. Of Fattening Sheep and Lambs.

7213. *The subject of fattening sheep may be considered in regard to the age at which fattening is commenced, the kind of food, and the manner of supplying it.*

7210. *The age at which sheep are fattened depends upon the breed, some breeds such as the Leicester, maturing at an earlier age than others, under the same circumstances; and also in the abundance and quality of the food on which they are reared, a disposition to early obesity, as well as a gradual tendency towards that form which indicates a propensity to fatten, being materially promoted by rich food, while the young animals are yet in a growing state. On good land, the Leicester wethers are very generally brought to a profitable state of fatness before they are eighteen months old, and are seldom kept for fattening beyond the age of two years. The Highland breeds, on the other hand, though prepared, by means of turnips, a year at least, before they are put to the stambles when from three to four years old. The ewes of the first description are commonly fattened after having brought lambs to foot three seasons, that is, after they have completed their fourth year and those of the small breeds, at from five to seven years of age, according to circumstances. (*Sup. & Brit. art. Agr.*)*

7211. *The kinds of food on which sheep are fattened are good pasture, permanent or temporary herbage crops, as clover, turnips, &c.; turnips and other roots and mixed cake, grains, or other edible refuse of the oil manufactory, brewery and distillery.*

7212. *The mode of feeding on rich pastures, herbage, and turnips has already been described when treating of these crops, and it remains only to notice the modes of using grains and oil cake. These, and also bran, oats, peas, and other grains and meals, whether given in winter or summer should always be accompanied with pasture or dry food of some sort, especially hay. All food of this sort should be given in moveable troughs, dividing in the middle, so that the sheep may feed on each side, with a sloping roof over them, so as to cover the sheep's heads and necks while feeding as wet is not only prejudicial to the sheep but spoils the food. A rack for hay fixed over the trough might probably be made to answer in this intention, while it would be very convenient for holding that material and preventing waste. The wheels should be fixed on wheels and made to stand steady and a sufficient number for the quantity of sheep be always in readiness. In the fattening of wethers the use of barley meal, with grass or some other sort of green food, has likewise been found highly beneficial; and when it can be procured at a reasonable rate, should not be neglected, as it is quick in rendering them fat, and the mutton is excellent. A pound of oil-cake or of meal per day with hay or turnips, for each crock or wether, is reckoned a fair allowance in Lincolnshire. In the report of that county several instances of oil-cake feeding are given by which it appears that that sort of food fattens in a shorter time than any other in the most suitable food for fattening old sheep, and a rapid promoter of the growth of the wool.*

7213. *In fattening sheep as well as other animals, it should be made a rule never to allow them to lose flesh, from the earliest age till they are sent to the butcher. It is found of much advantage with a view to speedy fattening as well as to the economy of food, to separate a flock into divisions, corresponding with its different ages, and the purpose of the owner as to the time of carrying them to market; and the change from the food of course to fattening stock, from that which is barely capable of supporting the condition which they have already attained to that which is adapted to their speedy improvement in fattening, ought to be gradual and progressive. Thus very lean sheep are never, in good management, put to full turnips in winter nor to rich pasture in summer they are prepared for turnips in good grass land; when on the other grass of mown grounds and kept on second year's leys, and afterwards a moderate allowance of turnips if they are fatted on pastures. It is a common practice in the instance of the Leicesters, to keep all that are not meant for breeding always in a state of fatness, and after full feeding on turnips through winter and spring, to finish them on the first year's clover early in summer when the prices of meat are usually the highest.*

7214. *The fattening of lambs during summer requires nothing more than keeping their mothers and them on the richest and best pasturage, and supplying such artificial food as the situation, season, or other circumstances may require but the fattening of lambs during winter and spring requires attention to three things the breed, or if any breed be used indifferently the period of dropping, the lamb-house, and the feeding.*

7215. *With respect to the breed as the sheep will take the ram at any season, any variety may be so managed as to drop their lambs at any period of the year; but it is found by experience, that the Dorsetshire sheep is earliest made to yearn, and therefore this is the sort generally employed in Middlesex for rearing what is called house-lamb for the metropolis. The selection of the rams for breeding the lambs to be house-lamb is, according to Middlesex, founded on the following circumstances. The rangers, shepherds, and butchers of London are aware that such lambs as have sharp horns on the inside of their lips are certainly of a deep colour after being butchered, and that all those whose horns are naturally blunt do so certainly produce fair meat. This knowledge has been the occasion of many lambs of the latter kind being kept for rams, and sent into Dorsetshire expressly for the purpose of improving the colour of the flesh of house-lamb; the bone of such rams can generally be warranted fair and such meat always sells at a higher price; hence arose the mistaken notion that Middlesex rams were necessary to procure house-lamb.*

7216. *A lamb-house may be any close shed, cow-house, or other spare house, or even on a small scale, a roomy pigsty. But they are built on purpose by the extensive dealers in this article; and one to suckle from one hundred and sixty to one hundred and eighty lambs at a time should be seventy feet long and eighteen feet broad, with three ranges of different sizes at each end, so constructed as to divide the lambs*

according to their age. A plan of a sheep-house, containing also a lamb-house, is given by Knut in his *Sheep Husbandry*. It is wholly built of unglazed open or young brick-work. The plan (fig. 895) contains four close apartments with doors for the lambs (a), and four others with stairs for the sheep (b). The elevation

895

896

(fig. 896) shows a gallery (c) which surrounds the building, and is used as a passage for viewing the sheep, handling them with the crook, and at night for the perambulations of a watch dog. The roof being twenty feet from the floor the interior is abundantly airy which for sheep is an important object. Another design in the same work (fig. 897) is accompanied by an elegant Indian watch-tower, with apartments therein for the shepherd.

897

7257. *The economy of the rearing house is as follows* — The sheep which begin to lamb about Michaelmas are kept in the close during the day, and in the house during the night, until they have produced twenty or thirty lambs. These lambs are then put into a lamb-house, which is kept constantly well littered with clean wheat straw and chaff both in lump and in powder is provided for them to hot, in order to prevent looseness, and thereby preserve the lambs in health. As a prevention against gnawing the boards or eating each other's wool a little wheat straw is placed, with the care downwards, in a rack within their reach, with which they satisfy themselves, and of which they eat a small quantity. In the house they are kept, with great care and attention, until fit for the butcher.

7258. *The mothers of the lambs are turned, every night at eight o'clock, into the lamb-house to their offspring* — At six o'clock in the morning these mothers are separated from their lambs, and turned into the pasture, and at eight o'clock such ewes as have lost their own lambs, and those ewes whose lambs are sold, are brought in and held by the head till the lambs by turns suck them clean. They are then turned into the pasture, and at twelve o'clock the mothers of the lambs are driven from the pasture into the lamb-house for an hour in the course of which time each lamb is suckled by its mother. At four o'clock all the ewes that have not lambs of their own are again brought to the lamb house and held for the lambs to suck, and at eight the mothers of the lambs are brought to them for the night.

7259. *This method of suckling is continued all the year* — The breeders select such of the lambs as become fat enough, and of proper age (about eight weeks old) for slaughter and send them to markets during December and three or four succeeding months, at prices which vary from one guinea to four, and the rest of the year at about two guineas each. This is severe work for the ewes, and some of them die under excess of exhaustion. However, care is taken that they have plenty of food. For when green food (viz. turneps, rabe, rye, tares, clover, &c.) begins to fail, brewers' grains are given them in troughs, and second-crop hay in racks, as well to support the ewes as to supply the lambs with plenty of milk. For if that should not be abundant, the lambs would become stunted, in which case no food could fatten them. (*Middlesex Report*, p. 365.)

#### SECT. VII. Probable Improvement to be derived from Crosses of the Merino Breed of Sheep

7260. *The Merino, or Spanish variety of the Ovis Aries, is supposed by Romer and other French writers to have been originally imported from Africa to Spain*. It is, however, at least as probable that they are indigenous to that country or if originally imported, that they have become modified to what they are by the soil and climate.

7261. *Merinos first attracted attention in this country in 1764, in consequence of the reports of travellers, and a letter by Don John Bowley to Peter Collinson published in the Gentleman's Magazine for that year*. A few were imported in 1788 and more in 1791 and placed on the king's farm at Windsor under the care of Sir Joseph Banks, who was then constituted his Majesty's shepherd. The first sale of stock was made in 1800 and from thence, a flock imported from Spain in 1801 by Lord Somerville, and some other importations by different persons subsequently, have sprung all the Merinos and Merino rams in the empire. Since that period, a number of eminent breeders and scientific agriculturists have sought and the breed both alone and by crossing, but especially Dr Parry and Lord Somerville and though the utility which its introduction may ultimately prove to the country can by no means be estimated at present, that it has already done much good by directing the public attention to the subject there can be no doubt, and many are of opinion that by its feces of our short-woolled sheep may be so improved as to render them fit substitutes for imported Spanish wool.

7262. *Dr Parry's experiments with the Merino breed were begun nearly at the same time with the king's*. His farm was elevated, exposed, and unfit for any other purpose than breeding, and he fixed on the Ryeland breed, as one of the finest woolled varieties of British sheep, for crossing with Merino rams. His only object was the improvement of the fleece.

7263. *The effect of the fourth cross of the Merino ram, according to the opinion of sheep cultivators on the Continent, on any breed of ewes, however coarse and long as the fleece, will be to give progeny with short wool equal to the Spanish*. Of the truth of this proposition however, Dr Parry justly expresses some doubts, derived from his own experience and that of others. But it is certain, he adds, that one cross more will, in most cases, effect the desired purpose. If we suppose, he says the result of the union of the blood of the Merino ram to be always in an exact arithmetical proportion, and state the native blood in the ewe as 64 then the first cross would give  $\frac{1}{2}$  of the Merino the second  $\frac{1}{4}$  the third  $\frac{1}{8}$  the fourth  $\frac{1}{16}$  the fifth  $\frac{1}{32}$  the sixth  $\frac{1}{64}$  and so on. In other words, the first cross would have thirty-two parts in sixty-four or half of the English quality, the second sixteen parts, or one fourth; the third eight parts, or one eighth; the fourth four parts, or one sixteenth; the fifth two parts, or one thirty-second; the sixth one part, or one sixty-fourth and so on. Now if the elements of the Wiltshire, or any other coarse wool, be in diameter double that of the Ryeland, it is obvious, that, according to the above statement, it would require exactly one cross more to bring the hybrid wool of the former to the same fineness as that of the latter. This, he believes, very exactly corresponds with the fact. The dis-

between one eighth and one sixteenth is very considerable, and must certainly be duly noticed, both by a good manager, and in the cloth which is manufactured from such wool. In the latter method, however, "it certainly has been practised; but I have hitherto had no opportunity of trying the difference by directness. The fifth week, as I have before observed, brings the Merino-wool to the same standard as the fourth of the Merino Ryeland." (*Ann. to the Board of Agr. vol. v. p. 305.*)

7264. In the lambing season, the Ryeland breed are usually cotted, because the new born lambs are very thinly covered with wool. As January was considered the best lambing season for the produce of the breed, Dr. Parry found coting was doubly necessary. Every night the flock were well shelted and they were allowed, in addition to the pasture which they could pick up in the day time, instead of jolly greened clover, or grain, outcrops, reeds, winter and spring vetches, and tares. Selt, he says, I never gave to my flock but once, and that in the following way — A small field of lathemath, cut in September, and been as often watered, that I despaired of its ever being eaten. While it was getting into the root, I showed some selt between the layers — the consequence was, that cows and sheep greedily devoured it, scarcely leaving a single blade. (*Ann. to the Board of Agr. vol. v. p. 305.*)

7265. The shearing of the sheep was performed in the second week of June, and of the lambs at the end of July. The first second lambs need not be shorn till the second season. Washing previously to shearing Dr. Parry disapproves of, because the fleece is so thick, that when thoroughly soaked with water it is very long in drying; and if the weather prove wet and cold, the sheep are evidently much uncomfortable; he therefore recommends cleaning the wool, after being shorn, as in Spain.

7266. The produce of wool, considered as the result of Dr. Parry's well conducted experiments, was found to be 14 lbs. per acre, which he put in the work throughout the fleece gives 11 to 14d. per acre on land certainly not worth an average 50s. (*See Ann. to the B. of Agriculture, vol. 1.*)

7267. Lord Somersville's experiments may be considered as of equal, if not more importance than those of Dr. Parry. His Lordship tried crosses with several short-wooled breeds, but was most successful with the South Downs and Ryelands. Maria Birbeck, a professional farmer of the first order, found that the fleeces of the first cross between Merinos and South Downs, washed, are to the parent South Downs as six to five in weight, and as three to two in value per pound, and believes that the improvement of the wool may go on, without detriment to the carcase, until we shall obtain a breed of sheep with Spanish fleeces and English constitutions — but this must be the result of careful and judicious selection.

7268. Merino flocks are now established in most districts of the empire and but few years can elapse before their value to the farmer and the country be practically ascertained and evinced. (*See Sir J. Banks in Annals of Agriculture, Ann. to B. of Agr. Both Society's Papers, Dublin Society's Transactions, The Farmer's Magazine, Farmer's Journal. Lord Somersville's and Dr. Parry's Treatise on Wool and Merinos, and various other works.*)

#### Sect. VIII. Anatomy and Physiology of Sheep.

7269. The general structure of the sheep resembles that of the ox very intimately; Sheep however, like the ox, experience considerable variations in size, form and qualities resulting from the physical and moral agencies which they become exposed to, under various climates and also, as whether fostered by cultivation, or left to the natural operations of nature around them. These circumstances have operated on even the bony base of the machine, as we see in the formations of the three-horned breed (*Ovis polyacerta Linn.*) natives of the north, in the spiral-horned (*O. Strepsiceros Linn.*) which inhabit Wallachia, and the long horned (*Capra Ammon Linn.*) which are found in the countries bordering the Mediterranean — and which have been thought to be the parents of the present cultivated British sheep.

7270. *Quadrumanus* retains the otherwise inherent aptitude to retain the original stamp of nature — and we find, therefore, that by these means, the original form of the sheep has submitted to vast alterations. We see some of them wholly without horns, we also find that the bony structure is otherwise subjected to our command, by becoming much more slender though more compact. Accidents are also laid hold on by man to produce particular forms — thus a breed has been cultivated in America, called the ancon or angor breed, remarkable for crooked and deformed legs, which, by continued breeding from specimens that presented the originally accidental deformity is become now a fixed and permanent breed, valuable for their incapacity to wander or climb. (*Dwight*) The dunky or wry faced breed, is another instance of accidental deformity introduced into a permanent variety — as the monstrous rump of the Tartarian sheep, and the over-grown tails of some breeds in Turkey and the Cape of Good Hope are similar instances in the softer parts of the body.

7271. The skeleton of the sheep presents an assemblage of bones, which bears a general resemblance to that of the ox in number and direction. Like him, the head naturally is surmounted by horns springing from the frontal bones. Like him, his frontal sinuses are large and open, and thus liable to the entrance of insects. The skull bones are wide and extended, his orbits are more lateral than central, and his facial angle is about thirty degrees. His vertebral column is the same as the ox, and his ribs also. The extremities descend on the same construction, ending in a divided hoof.

7272. The visceral and soft parts are but little dissimilar likewise. His brain is as one two-hundredth to the whole body, and his cerebellum to the brain generally as one to five. The pigment of the eye is of a pale yellowish green, varying occasionally to a blue. The viscera of the chest correspond with the ox — and those of the belly also, the stomachs being the same, and the economy of rumination not differing. The liver, pancreas, and spleen are similar. The penis is taper and scutellum wanting, and prominent here.

7273. The coat of the sheep is but a crisped hair, and indeed in some foreign varieties, the outer covering is of long hair like that of oxen; while in others, the hair and wool are mixed.

#### Sect. IX. Diseases of Sheep.

7244. The diseases of sheep are numerous, for these animals are now so highly cultivated that they may be regarded in some respects as artificial machines — and thus, as a natural consequence, they are subjected to a variety of artificial defects or malaises.

7245. The rot is a popular term among shepherds, and includes within its range diseases widely different. We shall not, therefore, follow the custom of treating the different sorts of sheep together — but we shall allow them to fall in their natural order according to the plan pursued with the diseases of oxen.

7246. The *Scab* is a very common disease, particularly known by the names *highland scab* or *lowland scab*. It does not differ materially from the same disease in oxen and cows and is in sheep also sometimes attended appearing by pitting, dizziness, watery mucus from the nose and eyes — and great redness of all such parts as are usually white.

7247. The *red water* — The inflammatory fever sometimes resolves itself into an universal secretion of serum throughout all the vessels; in which case, after a few days, the lymph tinged with blood will come

away from the nose and mouth in large quantities. Sometimes after death the bloody serum is found scattered throughout the skin in the blood striking of skin.

7242. The *clonus* or *stomp* pax is also another variety of this disease, in which it takes on a particular form. About the third day small variolæ appear sometimes they are rather blotches than pustules. The weakness is usually extreme, and the putridity great. This form of the disease is seldom seen with us, but is still known on the Continent, where the pastures are very poor and low, and the general help meagre.

7243. The treatment of all these in nowise differs from that directed under the inflammatory putrid fever of the ox. The dose of medicine being about a third of what is directed for them.

7250. *Malignant epidemic or neuræmia.* Sometimes an epidemic prevails, which greatly resembles the murrain of oxen in appearance, termination, and treatment, it resembles the malignant epizootic of oxen. (664.)

7251. *Pneumonia or inflamed lungs, rising of the blights, glanders rot, heart, &c.* These terms are all modifications of an inflamed state of the viscera of the chest, caught by undue exposure, bad pasturage and often from over-driving. The cough, the tremblings, the redness of the eyes and nostrils, and the distillation of a fluid from them, with the heavings and hot breath, are all similar to those which characterize the pneumonia or rising of the blights in oxen. We remember to have seen the disease strongly marked in the February of 1803, on a farm in the neighbourhood of Stroudham, where several sheep were attacked almost together, after a very stormy night. They were first affected with a loss of appetite next with a fixed staidish look, which was common to every one. After this, they reeled about, fell backwards, and became convulsed. When seen five were already dead, whose internal appearances fully confirmed the nature of the disease. The rest recovered by bleeding and drenching, with drenches composed of nitre and tartar emetic. Sometimes the symptoms of pneumonia do not rise immediately but degenerate into an ulceration of the lungs which is then called the *glanders rot*. This stage is always fatal the others may by early attention, be combated by judicious treatment, as detailed under the same disease in oxen.

7252. A chronic cough in sheep, when not symptomatic of rot, is always cured by a change of pasturage, particularly into a salt marsh.

7253. *Inflammation of the stomach* occurs from various causes. A common one arises from eating poisonous vegetables and produces the affection termed *drunkenness*. It also produces the *gross rot* in lambs which latter is always accompanied with black fetid faces, and is readily removed by an ounce of castor oil while the former usually yields to half an ounce of oil of turpentine, beaten up with the yolk of an egg. Some herbs (as *A. tropæ Belladonna*) when eaten produce spasmodic affections, which are called by shepherds the *laquing ill*. In such cases, the watery solution of aloes (*See Pharm.* 6263.) in doses of two or three ounces is useful. Daffy's elixir we have also known to be given with good effect.

7254. *The howe blint or wind colic.* Sheep are as liable to be distended with an enormous collection within the maw as oxen. An instrument, similar to that invented by Dr. Moore, is also made for them and when not relieved by these means, the same remedies are applicable as are directed for oxen. (6553.)

7255. A *wound colic* will also sometimes affect sheep more from the quality than the quantity of what they eat. It is best relieved by an ounce of castor oil and oil with an ounce of gun.

7256. *Inflamed liver blood rot or hot gutters* are liver affections, arising from fever settling in that organ or from obstructed bile irritating it. Sometimes there are great marks of fever and at others more of putridity according to which, treat as may be gathered from ox pathology.

7257. *Jewandoe* also now and then occurs, when refer to that disease in oxen. (6562.)

7258. *Dysentery* and *scour*, *braxy* are all affections brought on by sudden changes of temperature, or of undue moisture acting with cold pasturage. It is often seen in sultry autumns and, by a judicious observer has been said to be particularly frequent in hogs or sheep of one year. Like other dysenteries it is frequent in sultry autumns. The above authority recommends, when its origin may be supposed to arise from a previous colic state, to remove the affected (as is practised by the store-masters of Scotland) into turnips. The general medical treatment does not differ from ox braxy. (6561.)

7259. *Scouring* is the diarrhoea of sheep, and in very hot weather soon carries them off. It should be early attended to, by abstracting the affected, and housing them. The treatment is seen under diarrhoea of oxen (6560.) which it closely resembles.

7260. *Furrowing* *lag drift* *lock-share*. The two former are only the adhesion of the tail to the wool and the excoriation brought on by diarrhoea the latter is the diarrhoea itself known to some by this term.

7261. *The rot in sheep* is also called *great rot*, and *Apyrotic rot* &c. but it is more popularly known by the simple term of *rot*. Many causes have been assigned for it, as the Fasciola hepatica, or fluke worm some particular plants eaten as food ground eating snails, and other ingesta but, as most of the supposed deleterious herbs have been tried by way of experiment, and have failed to produce the disease, so it is attributable to some other cause. Neither is there satisfactory reason to suppose that the fluke worm is the original cause of it, but a consequence, since we know that the biliary vessels of other animals, as the horses, asses, rats, &c. often have them and above all, because that they are not always present in the rotted subject. From long experience, and the almost invariable effect produced by a humid state of atmosphere, soil, and product, we are warranted in concluding these are the actual and immediate agents perhaps the saturated food itself is sufficient to do it. The morning dew has been supposed equal to it. Bakewell, when his sheep went past service used to rot them purposely that they might not pass into other hands. This he always readily did by overflowing his pastures. But great differences of opinion exist as to the quantity, form, and varieties of moisture, productive of this fatal disease. It is said that land on which water flows but does not stagnate, will not rot, however moist but this is contradicted by the experience of Bakewell, who used merely to flood his lands a few times only to rot his sheep. It is also said that they are safe from rot on Irish bogs, salt marshes and spring flooded meadows, which experience seems to verify. It is also said that the very hay made from unsound land will rot but this wants confirmation. When salt marshes are found aqueous, it is only in years when the rain has saturated or rather super saturated such marshes. That putrid exhalations unaccompanied with moisture can occasion rot wants confirmation also for these commonly go together and it is difficult to separate their effects. It is not, perhaps, the actual quantity of water immediately received by land, but the capacity of that land to retain the moisture, which makes it particularly of a rotting quality.

7262. The signs of rot in sheep are sufficiently familiar to persons about sheep. They first lose flesh, and what remains is flaccid and pale they also lose their vivacity. The naked parts, as the lips tongue, &c. look livid, and are alternately hot and cold in the advanced stages. The eyes look red and glassy the breath is head, the urine small in quantity and high coloured and the bowels are at one time costive, and at another affected with a black purging. The pelt will come off on the slightest pull in almost all cases. The disease has different degrees of rapidity but is always fatal at last. The difference in degree occasions some rotted sheep to thrive well under its progress to a certain stage, when they suddenly fall off, and the disease pursues the same course with the rest. Some farmers know this crisis of declension, as it has been called and kill their sheep for market in the immediate sick of time with no loss. In these cases, no sign of the disease are to be traced by ordinary inspection, but the exposure of the flukes, and still more, a certain state of liver and of its secretions, are characteristic marks to the wary and experienced.

7263. The treatment of rot is seldom successful unless when it is early commenced or when of a mild nature a fatal change of food is the first indication, and of that to a dry wholesome kind. All the farms are good as the maw of wheat barley oats, peas, beans &c. Carrots have done good mixed with these

beams, burned, thin, and soft, as direction, have also been recommended; but it is necessary to observe, than there is seldom any relief but in the latter stages of the complaint. As long as the liver is not wholly diseased, the cure may be hoped by a simple removal of the cause, which has been shown to be a variable temperature, with excessive moisture of pasturage, which may also be aided by such remedies as assist the action of the biliary system. Salt acts in this way and thus salt meadows are good; salt may also be given in the water. Salt appears the principal ingredient in Fresh's patent restorative for sheep. He it states it to be composed of sulphur, oil of sweetgum, turpentine, quackquiver, kalmia, stone, salt, opium, almost ripe bark, sulphur, camphor, and distilled water. But of this medicine none of the authors can be in sufficient quantity to prove useful but the salt. In the more advanced stages of the disease, when the liver has become materially affected, it is prudent to rub the belly of each sheep with half a drachm of mercurial ointment every other day for a week. Give also the following, every morning. — Waxy mixture of aloes, half an ounce, decoction of willow bark, four ounces, nitric acid twenty-six drops.

7264. *The pot rot, jaeger rot or mated disease* is a variety of the former but with this difference, that whereas the liver in the hydatid rot is principally affected, in this the whole of the chyliferous viscera are affected, the mesenteric glands are always swollen and obstructed, and from thence arises the emaciation and unhealthy state of all the secretions, by which the wool becomes incapable of receiving nutriment, and falls off, leaving the body bare, and in the last stages the teeth and horns also become in different, unhealthy shape is a very common cause of this malady, and a contrary course of feeding is the best remedy when the disease has not gone on too long.

7265. *The scab, wheal, rag, or rubbers*, are sometimes erythematous eruptions, and sometimes they are pemphig or mangy ones. In the former instance they are universal and very red, commencing a great heat and itching, and are thence called the rubbers. In such cases, nitre administered quickly relieves, with change of food. The eruptive scab is seldom cured without an external application. Either of these directed for mange, lowered to half the strength, will relieve it at once (*See Vet Pharm*).

7266. *Foot rot*. Sheep have a secretory outlet between the claws peculiar to them, which is liable to become obstructed for which soaking in warm water and afterwards wrapping up the foot, having first dressed it with tar is sufficient. The feet of sheep are also sometimes injured by long traveling, when the best treatment is proper. The most serious foot rot is that which is in some instances, simply produced by a long-continued series of humid weather, which predisposes the feet to the injury. In others it appears to be both epidemic and endemic, and has been thought contagious. When the season has been unfavourable, horses and soil under cover. The medical treatment consists in removing all diseased portions, and then dressing with the thrush paste, or foot-rot application (*Vet Pharm*, 6556) and afterwards wrapping up from external exposure. Professor Fleming states the following application. — Take two parts of tar and one of oil of turpentine, which having mixed, one part of auriferous acid, known as oil of salt, is to be added slowly to which afterwards add four parts of blue vitriol, with which dress the affected feet. (*Journal de Med. Vet. de Comp*).

7267. *Stingers, gad, turnack, guggles, worms under the horn, stony watery head, and pondro*, are all popular terms for hydatids, or an animal now known as the *Linnæus globulus*, which, by some unaccountable means, finds its way to the brain, and twines itself there, either in some of its vesicles, or more frequently on its substance. Their size varies from the smallest speck to that of a pigeon's egg, and the sheep it attacks are usually under two years old. These animals are likewise occasionally found in all the natural cavities of the body.

7268. *The appearance of cerebral hydatids* are, stupidity, a disposition to set on the rump, to turn to one side, and to incline the head to the sun while at rest. The eyes glare, and from oval the pupils become round. An accurate examination will now usually discover some softness at a particular part of the skull, usually on the contrary side to that on which the animal bangs the head when no softness of the skull is discernible, the hydatid usually exists in some of the ventricles, and the destruction of the sheep is certain and quick, from the greater disturbance to the functions of the brain. But when it is situated on the surface, it sometimes requires many months to destroy, an absorption of the bone taking place as the hydatid increases, which produces the thinness in the skull opposite to the affected part.

7269. *This disease is not incurable* as has been supposed but it is only relieved by a manual operation. In France it has been successfully treated by the application of the actual cautery. A pointed iron, heated red-hot, is forced through the skin and skull, to the surface of the brain, the principal artery of which is penetrating the hydatid with the hot iron without wounding the brain itself. In England, some shepherds are very dexterous in curing, which they do by thrusting a wire up the nostril till it rests against the skull. In the passage of the wire the hydatid is usually ruptured, others elevate the skull (by means of a trephine, or even a knife) opposite to the softened portion, and extract the hydatid, if possible, whole, which a little care will effect, by drawing it away with a blunt pincer gently moving it from side to side. Tapping is merely letting out the fluid contents of the hydatid by an awl, which is practised by some shepherds with success, and if the instrument be not thrust far the sheep is not injured to avoid which, it is passed obliquely. A well barbed point is a very proper instrument, with which the skull is easily penetrated, and an opening by the twisting of the instrument is made, sufficiently large in the hydatid itself, to discharge its contents, which is all that is sufficient to ensure its destruction and which, if no other exists, is followed by immediate recovery. A French author states, that when he fed his sheep on mangrove he had less staggers than at any other time.

7270. *Spontaneous worms*. Sheep are observed to gather together with their noses thrust upwards to avoid the attack of the *Ostrus* bry, or fly that lays its egg on the inner margin of the nose, which having become heated, the horns creep up into the frontal and maxillary sinuses to the summit of the sheep, and sometimes to their speedy destruction. The Continental shepherds trap an opening into these cavities, and effect their removal but our shepherds have not succeeded in the operation.

7271. *Fluke worms* are a parasitic animal, found in the biliary passages, not only of the sheep, but of the horse, man, goat, deer, &c. and whose existence is rather a consequence than a cause of morbidity.

7272. *Phlegm, the Phlegm in Galloway* (Jaundice) is a disease described by Mr. Hogg, the Ettrick shepherd, in a recent number of the *Quarterly Journal of Agriculture*, xi. p. 607. He says, "It is most fatal in a season of drought and June and September are the most deadly months. If ever a farmer perceives a flock on such a farm having a flushed appearance of more than ordinarily rapid thriving, he is gone. By that day night days, when he goes out to look at them again, he will find them lying, hanging their ears, running to the eyes and looking at him like so many condemned criminals. As the disease proceeds the hair on the animal's face becomes dry the wool assumes a bluish cast, and if the shepherd have not the means of changing the pasture, all those affected will fall in the course of a month." (*Quarterly Jour. Agr. High. Soc. vol. ii. No. XI.*)

7273. *The diseases of lambs* are principally indigestion, producing sometimes colic, which is relieved as in sheep, and sometimes diarrhoea, to be likewise cured by the means detailed for them. Sheep at about three to four months of age are liable to a disease, which gradually extends along the spine, and when it becomes more universal, it usually destroys. The cure consists in giving daily drunks of half a drachm of cream of tartar, and one drachm of sulphur, in four ounces of chamædorea decoction. Amount also with mild mercurial ointment and Turner's ointment in equal quantities. Lambs dropped in cold weather or in wet situations, become puffy, baths in warm water hand-rub and house, giving milk and bean meal,

## CHAP. VII.

The Swine. — *Sus Scrofa* L. Cochon, Fr ; Schwein, Ger ; Puerco, Span., and Porco, Ital.

7874. Of swine there are several species, but none in general domestication, or much used as food when taken wild, excepting the common sort, which includes the wild hog or wild boar, the original stock of our domestic breed, the European hog and the Chinese hog.

7875. The common hog is found either in a wild or domestic state, in almost all the temperate parts of Europe and Asia, but it is not met with in the most northern parts of these continents. It is found in many parts of Africa. Mr. Pennant asserts, that the wild boar was formerly a native of this country, but hunted from the middle of November to the beginning of December — and it is asserted by *Fitz-Maclean*, that the vast forest which in his time grew on the north side of London, was the retreat of stags, wild boars, and bulls.

7876. The wild boar is still found in the forests of Germany and in other parts of the Continent — and

696

although now extinct in Britain appears from ancient paintings (*Ag. Ins.*) to have been hunted by our ancestors. It feeds upon roots, acorns, and other vegetables. It is generally as large as the domestic hog, and is either dark grey or blackish when full grown, and pale red or rusty brown when young. Between the bristles, next the skin is a finer or softer hair of a woolly or curling nature. The snout is somewhat longer in proportion than that of the domestic animal, but the principal difference is in the superior length and size of the

bristles, which are often several inches long, and capable of inflicting the most severe and fatal wounds. The hunting of the wild boar forms one of the principal amusements of the great in some parts of Germany, Poland, &c. and is a chase of some difficulty and danger, not on account of the swiftness but the ferocity of the animal. Wild boars, according to Buffon, which have not passed the third year, are called by the hunters beasts of company because previous to that age they do not separate but follow their common parent. They never wander alone till they have acquired sufficient strength to resist the attacks of the wolf. These animals when they have young, form themselves into flocks, and it is upon this alone that their safety depends. When attacked the largest and strongest front the enemy, and by pressing all round against the weaker force them into the centre.

7877. Of the same hog, white is the most general colour, but other colours are often intermixed in various proportions. In some respects, the hog seems to form an intermediate link between the whale and the cloven footed animals, in others he seems to occupy the same rank between the cloven footed and digitated. Destructive of horns furnished with teeth in both jaws with only one stomach incapable of ruminating and producing at one birth a numerous progeny — the union of these faculties confers on the hog a remarkable peculiarity of character. He does not, like other animals, shed his fore teeth and put forth a second set, but retains his first set through life.

7878. Hogs seem to enjoy none of the powers of sensation in any great perfection. They are said to hear distant sounds and the wild boar distinguishes the scent of the hunter and his dogs, long before they can approach him. But so imperfect is their feeling that they suffer mice to burrow in the fat of their backs without discovering any uneasiness, or appearing even to notice it. In their taste they show a singular degree of voracity. In the choice of herbs they are more delicate than any other herbivorous animal yet devour the most nauseous and putrid carrion with more voracity than any beast of prey. At times they do not scruple to eat their own young — they will even mangle infants out of desperate voracity.

7879. Hogs are remarkable for the smallness of their eyes — hence a person whose eyes are very diminutive, and deep sunk in his head is said to be pig eyed. The form of the hog is inelegant, and his carriage is equally mean as his manner. His unwieldy shape renders him no less incapable of swiftness and sprightliness, than he is of gracefulness of motion. His appearance is always drowsy and stupid. He delights to bask in the sun and to wallow in the mire. An approaching storm seems to affect his feelings in a very singular manner. On such an occasion, he runs about in a frantic state, and utters loud shrieks of horror. Hogs are infested with lice, and are subject to many disorders, such as the scurvy scab and scrofula. The sow brings forth in the beginning of the fifth month after conception, and she has often two litters in a year. She generally produces a numerous progeny at a birth, but her first litter is less numerous than those that follow. Hogs, when suffered to see the natural term of life, live from fifteen to thirty years. Their size and strength continue to improve till they are five or six years old.

7880. Some hogs are often very troublesome in cultivated grounds, ploughing them up with their snouts, and thus entirely frustrating the labour of the agriculturist. Worms, the wild carrot, and other roots, are the objects of their search. The wild boar having a longer and stronger snout than the domestic variety digs deeper and continues his furrow nearly in a straight line. The inhabitants of America find the hog very beneficial in clearing their lands of rattlesnakes and other serpents, upon which he constantly preys, without apparently suffering any injury.

7881. The hog, as a very common and agreeable food, is much used. His flesh is pleasant, substantial, and nutritious, it affords numberless materials for the table of the epicure. Among these is brawn which seems peculiar to England. Pork takes salt better than the flesh of any animal, and is, in consequence, preserved longer and always makes an important article in naval stores. The lard of the hog is essential to the cook and confectioner, it is used in various medical preparations, and is compounded by the physician into pomatum. The bristles are made into brushes and are, moreover, of great use to the shoemaker. The skin is worked into coverings for pocket-books, and other articles.

7882. The hog as British farming is in general viewed as a subordinate species of live stock, and chiefly valuable as consuming what would otherwise be lost. There are, however, some husbandmen who keep large herds to advantage, especially millers, brewers, distillers, and dairymen to whom they are an object of importance — and reason, for the corn they consume, a greater weight of meat, according to some doubts the weight, than could be obtained from cattle. In those parts where potatoes are raised as a fallow crop, much beyond the demand for them as human food — as is the case in particular in Ireland, and the west of Scotland — the rearing and feeding of swine, the most of them sent to a distance in the state of bacon and pickled pork, is a branch of management on which great dependence is placed for the payment of their rents and other charges. The prolific nature of this animal, however, rendering it so easy to overstep the supply beyond the demand, the price of swine flesh varies more than that of any other sort of butcher's

most, and their culture can never be so much depended on by the general farmer as that of cattle or sheep. A writer in the *Farmer's Magazine* observes, that the swine are the only variety of granivorous animals that can be fed upon the sale of grain, or such articles as would otherwise go to waste about a farm-shedding. Since the invention of threshing machines, a much greater quantity of light grain is lost from the straw than was gained when the *bell* was employed. I propose this extra quantity to advantage becomes an important resource to the owners of land, and this writer thinks that the using of it for raising and supporting swine is by far the most profitable mode of consuming an article, which, in other respects, is comparatively of little value.

### SECT. I. Varieties of the Common Hog.

7283. The domesticated European variety of the common hog (fig. 898) is too well known to require any description.

7284. The Chinese hog (fig. 900) is distinguished from the common, by having the upper part of its body almost bare, its belly hanging nearly to the ground; its legs are very short, and its tail still more disproportionately short. The flesh of this variety is whiter and more delicate. The colour is commonly a dark grey. It

abounds in China, and is diffused through New Guinea, and many islands in the South Sea. The New Hebrides, the Marquesas, the Friendly and the Society Islands, possess this animal, and cultivate it with great care, as it is almost the only domestic animal of which they can boast. The varieties of hog cultivated in Britain, are partly the result of climate and keep in the European variety, and partly the effects of crossing with the Chinese. At the same time, it is only in particular districts that so much attention has been paid to this animal, as to give rise to any accurate distinction of breeds; and nowhere has it received any considerable portion of that care in breeding, which has been so advantageously employed on the other animals of which we have treated. Yet among none of the varieties of those is there so great a difference as among the breeds of this species, in regard to the meat they return for the consumption of a given quantity of food. Some races can with difficulty be made fat, even at an advanced age, though fed from the trough with abundance of such food as would fatten any other animal, while others contrive to raise a valuable carcass out of materials on which no other creature could subsist.

7285. The Chinese race according to Culley has been subdivided into seven varieties or more, and it would be easy to point out twice the number of as prominent distinctions among the sorts in the third class. But such an affectation of accuracy is as useless as it would be tedious. One general form, approaching to that of other animals kept for their carcass, ought certainly to be preferred, and the size, which is the other distinguishing characteristic, must be chosen with a view to the food provided for their maintenance, and not because it is possible to raise the individuals to a great, and probably superfluous weight. The fineness of the bone, and the breed, though also deep, form of the chine, denote in this, as in the other species, a disposition to make fat with a moderate consumption of food and while it may be advisable to prefer the larger breeds in those places where bacon and hams are in most demand, the smaller breeds are most esteemed for picking and are beyond all doubt, most profitable to those farmers who allow them little else than the range of the farm-yard and the offals of the kitchen.

7286. The Berkshire breed (fig. 901) is distinguished by being in general of a tawny white or reddish colour spotted with black, large ears hanging over the eyes thick, close, and well made in the body legs short small in the bone, having a disposition to fatten quickly and when well fed, the flesh is fine. Berkshire has been long famous for its breed of swine, which, as it now stands, is, in the third class, in point of use, excellent in all respects, but particularly as a cross for heavy slow-fattening sorts. It has extended itself from the district from which it takes its name over most parts of the island. It is the sort mostly fattened at the distilleries, feeds to a great weight, is good for either pork or bacon, and is supposed by many to be the most hardy both in respect to their nature and the food on which they are fed.

7287. The Hampshire breed (fig. 902) are large, longer in the body and neck, but not of so compact a form as the Berkshire, they are mostly of a white colour or spotted, and are well disposed to fatten coming up to a great weight when properly managed in respect to food. Lawrence says they are generally dark spotted, some black, of a longer and fatter make than those of Berkshire, ears more pointed, head long and sharp resembling the Essex.

7288. The Shropshire breed is another large breed of hogs, which are found valuable where the keep is in sufficient abundance for their support. They are not so well formed as those of the Berkshire kind, or equal to them in their disposition to fatten or to be supported on such cheap food. The standard colour of this breed is white, or belindeed Shropshire has long bred stores for the supply of the London fenders, and of the Essex farmers, who thus turn their clovers to the most profitable account.

7289. The Gloucestershire breed is likewise a larger breed, but inferior to either of the above, being tall and long in shape, and by no means so well formed. The colour is in general white. It has two varieties hanging from the throat.

7290. The Norfolk breed (fig. 903) is also a large useful breed, but perhaps without possessing any advantage over those that have been described above.

7291. The Bedfordshire breed is a large kind of swine, which the author of the *Survey of Bedfordshire* says is the largest in the island, next with the village of that name on the borders of Leicestershire and Bedfordshire. They feed to an extraordinary size, and weigh at two years old, nearly double or triple the usual weight of other sorts of hogs of that age. As large breeds pay the farmers best in many cases such a breed deserves to be attended to in the system of hog management.

7292. The large spotted Wiltshire breed is a breed introduced by the late Duke of Bedford being large in size and of various colours. It is a hard, well formed, prolific sort, rising quickly to a large weight.

7299. *The Wiltshire breed* is a long-bodied, low hog, hollow about the shoulder, and high on the rump, muddling large pointed ears, round bone, light in colour.

7300. *Yorkshire breed*. This, in the old breed, was probably the worst large variety we had extremely long legged and weak-boned, their constitution not of the soundest, and bad stop-pigs in the winter season they were yet quicker feeders than some of the superior breeds. They have been improving some years from the Berkshire cross, but are still inferior to the north-western stock, rendering a less price at market.

7301. *The Northamptonshire breed* was formerly a handsome, light-eared, white, deep-sided pig, with muddling bone and quick of proof the breeders have since tried the new Leicester.

7302. *The Leicestershire breed* is, in the original stock, large, deep, and flat-sided, light-spotted, with rather handsome head and ears. The Bakewell variety has much merit.

7303. *The Lincolnshire breed* was formerly light-coloured and white, like those of Northamptonshire, many of them having curled and wavy coats. They are middle-sized quick-growing pigs.

7304. *The Norfolk breed* is a small, short, up-eared porking sort, various in colour white bluish, striped, generally an inferior kind, which it could be to the interest of that great corn county to improve they are, however, of a thin-skinned quick-proving kind. But in the vicinity of Lynn, and generally on the Lincoln side of the county there is a larger spotted variety of very good firm and quality which should be encouraged.

7305. *Suffolk breed*. (Ag. 504.)

504

This is a small, delicate, white pig, which has for many years had great reputation and at this time there is not only a strong prejudice in their favour in their own county but they have many advocates out of it. They are shorter and more pug formed than the Northfolds, and by their dish-face, and pendent belly it may be supposed that the variety proceeded originally from the white Chioses. Some of the Suffolks are very handsome, and very regularly shaped.

7306. *The Essex breed* are up-eared, with long sharp heads, rock-backed, carcases fat, long, and generally high upon the leg, bone not large, colour white or black and white, bare of hair quick feeders, but great consumers and of an inquiet disposition.

7307. *The small, white English breed* is met with in many districts; it is of a white colour thick, compact, and well made in the body short in the leg the head and neck well formed, and the ears douch-

ing a little downwards. It is well disposed to fatten, and perfectly hardy. It prevails much in the northern districts.

7308. *Swamp tailed breed*. This is a useful sort of the smaller kind of hogs, hardy in its nature, and of considerable weight in proportion to its size.

7309. *There are many other varieties and subvarieties in England* which it is unnecessary to notice here. Donaldson remarks, that the Berkshire and Hampshire hogs are the largest but that it is most probably from the Berkshire stock that the greatest number of the varieties of the country have sprung.

7310. *Of the Highland breeds* that of the Hebrides supposed by Dr Walker to be the original, is of the smallest size, neither white nor yellow but of a uniform grey colour and shaggy with long hair and bristles, they graze on the hills like sheep their sole food is herbage and roots and on these they live the whole year round, without shelter and without receiving any other sustenance. In autumn when they are in the best order their meat is excellent, and without any artificial feeding but when driven to the low country, they fatten readily and rise to a considerable bulk. (Walker's Hebrides, vol. i. p. 17.) In the Orkney Islands they are commonly of a dark red or nearly black colour and have long bristles, with a sort of coarse wool beneath them.

7311. *The old Irish breed* are a long-legged thin sided lank haggard, unprofitable sort of swine but where they have been crossed with the Berkshire, they are considerably improved.

## SECT. II. Breeding and Rearing of Swine.

7312. *In the breeding of swine*, whatever be the variety the most perfect and best formed boar and sow should be chosen and a due regard paid to their age, time of copulation, period of gestation, farrowing castrating or spaying and weaning.

7313. *In choosing the boar and sow* regard must be had to their size, as well as perfection of form. Where food is abundant, or the object of the progeny is the production of bacon and fleshes the larger breeds, as already observed, are to be preferred but where food is scarce or uncertain, as in the case of the cottager's stock, or rearing for suckled pork, fresh pork or pickled pork the smaller breeds, as the Berkshire, are to be preferred. A breeding sow ought to have a large capacious belly and not to be too much inclined to obesity. To check this tendency some allow them to breed five times in two years.

7314. *The age of the boar* should not be less than a year so he will them be at his full growth nor that of the female less than two months. They may be used in breeding for three or five years, and then fed off for the shambles.

7315. *The period of gestation* in swine is about four months, so that two litters may be easily produced in a year, five in two years, or ten in four years.

7316. *The best times for copulation* are November and May because then the progeny are brought forth in mild weather and when green food is to be had. They should not be allowed to farrow in winter as young pigs are exceedingly tender and can with difficulty be preserved in very cold weather nor at a time when food is scarce as is generally the case upon corn farms in summer if the stock of them is large. When the object is suckled pigs for the shambles, copulation should be so contrived as to produce parturition at all seasons.

7317. *The usual produce* is from about eight to ten or twelve pigs in the large but more in the smaller breeds, which in general bring the greatest number and the most early. Twenty swine are estimated to bring at an average seven pigs and a half each for their first litter but the number varies much and many young pigs are lost soon after their birth by the unkindness of their dam, and by casualties, to which they are more exposed than most other young animals.

7318. *The pregnant sows* should be separated from the herd some time before she is expected to farrow carefully watched and interval with a small quantity of dry short straw. Too much exercise is improper, both at the time of farrowing, and for a week or two afterwards, as the pigs are apt to nestle beneath it unperceived by the sow and are thus in danger of being smothered when she lies down. A breeding sow should be well fed, particularly when nursing and it is advantageous early to accustom the pigs to feed from a low trough on milk or other liquid food, mixed with meal or bran. Each of the pigs of both sexes as are not to be kept for breeding are usually castrated or spayed when about a month old, and the whole may be weaned at the end of six or seven weeks.

7319. *The food allowed to growing sows* depends in almost every case upon the circumstances of their owners for as already observed, it is a doubtful point whether swine will pay when all their food both in rearing and feeding is to be purchased. The cottager's pig must be contented with the scanty offer of his kitchen and of his dairy the produce generally of a single cow. Towards the end of autumn a few potatoes are added for the purpose of preparing it for the slaughter, and perhaps a little meal is raised with boiled potatoes for a week or two before. Such pigs however often thrive amazingly make themselves remarkably fat, and form a most valuable addition to the winter stores of their owners. In the south-eastern

counties of Scotland, the hind or married ploughman are commonly allowed to keep a pig each, which they feed in the winter, and from which their families derive much benefit at very little expense. Near wheat, barley, malt, and other seeds, as well as some roots and vernal, afford excellent nourishment. On many corn farms, the chaff, and not unfrequently the only dependence of swine is on the straw yards. The sweepings of the barn floor, corn left upon the straw, and oats found among the dung of horses, with a share of the turnips given to the cattle in winter, and of the clover in summer afford ample subsistence to swine, in the proportion, perhaps, of one to every five or six acres under corn, clover and turnips. The kitchen and dairy give some assistance to pigs newly weaned, and also to such as are soon to be slaughtered. A great many are killed when about a year old, but have never been fed at any expense that can be estimated. A few pigs, if of a good breed will always be moderately fat at that age with the run of the straw-yard, and their flesh is of an excellent quality.

7514. To prevent *swine from digging* in the soil, the best method is to cut the two strong tendons of their mouths with a sharp knife, about an inch and a half from the nose. This may be done with little pain, and no prejudice, to the animal when about two or three months old. The common practice of restraining them by rings fixed in the snout is painful and troublesome; they must be replaced as often as they give way and that happens so frequently that rings afford but little security against this nuisance.

### SECT. III Fattening of Swine.

\*7515. The following system of rearing and fattening swine on an arable farm is recommended by a writer in the *Farmer's Magazine*.

7516. Upon a *single farm* consisting of three hundred acres, whereof two hundred are kept under the plough, he is of opinion that a considerable sum may be annually gained from keeping swine, were the management arranged in a systematic manner. One main advantage of such a branch of rural economy arises from little or no capital being required to carry it on, while the trouble and outlay attending it scarcely deserve notice. With the addition of one acre of broad clover and one acre of bare, for the summer and autumn months, and the like extent of ground for turnips and yams during the winter and spring months this stock of swine may be amply supported.

7517. Were two breeding sows kept on a farm of the size mentioned, and their produce reared by the farmer, it may be calculated that forty swine, weighing seven or eight stone each would be annually fed off, in the month of January and February each year the time when pork is most in demand. That such a number of swine can be supported and fed upon the offals of a three-hundred-acre farm, and the other auxiliary articles specified, may be pronounced a certain fact.

7518. The breeds he recommends are the hardy smaller sized varieties because he has found that such breeds will thrive and grow fat where larger and finer breeds would starve.

7519. The mode of management is, that a boar and two good sows of a proper age should constantly be kept, and that one young one shall annually be reared, in order to supply the others when they pass maturity. He would cast off the oldest sows, &c. feed them when they arrive at three years of age which, of course, would cause four sows to be in hand at one time. These annually would produce more than the forty pigs which are to be held on but the remainder might be sold as they are wanted, there being a regular and steady demand in most parts of the country for young pigs. He has for a number of years kept a stock of swine in the way recommended. They go at large in the court or yard belonging to the farm, and receive a feeding of offal grain in the morning and of yams or turnips in the evening, and the meat fed in this way has constantly drawn the highest price. They get also the dish washings of the house, any milk or whey that remains unconsumed, and have the dunghill to roam upon, where perhaps more food is to be gathered, especially if the horses are fed upon unbroken grain, than is commonly imagined. It will readily be concluded that, under this mode of management, the latter end of summer and the harvest months is the critical period for carrying on a stock of swine. During these months little threshing goes forward and horses seldom receive any corn for aliment, hence all that can be conveniently attempted is to keep the animals in a growing state, and prepare them for fattening cleverly when food of a more nutritious quality can be procured. Clover and tares will do this effectually the last particularly so when in a podded state. Turnips can also be got by the end of September and it must be recollected, that through the summer months a considerable quantity of milk and whey can be given, upon which swine will be found to thrive heartily. He does not know a more beneficial stock upon a farm than swine, so long as the quantity kept is in proportion to the extent of offals about the premises. The other articles recommended are merely meant to render the consumption of offals more beneficial, to carry on the stock at periods when such offals are scarce. The charge of attendance is very small indeed, the benefit gained by the dunghill will more than compensate the expenses incurred. To make as much profit from cattle or sheep requires a great advance of money, but in the article of swine hardly any is necessary while the most part of the articles consumed cannot, in any other way be converted to such beneficial purposes.

7520. In fattening for bacon and pickles the larger breeds are chosen, and in breweries, distilleries, salvers, and dairies, fed on grama, oil cake, and milk but where arable farmers keep swine of this description, as is the practice in some of the western counties, the method is to rear chiefly on raw potatoes and Swedish turnips, and to fatten on these roots, beets or prepared by steam, with a mixture of oat, barley or bean and pea meal. Their troughs should be often replenished with a small quantity of food at a time, and kept always clean and their food changed occasionally and seasoned with salt. If proper care be taken, says a late writer a feeding pig should not consume more than six Winchester bushels of oats made into meal. It ought to be shelled before it is ground, the same as for family use, but need not be sifted. (*Howderson's Treatise on Swine* p. 23.)

7521. In fattening suckling pigs, all that is requisite is to keep the mother well lodged and nourished. Weaned pigs when to be fatted are kept constantly on whey or skim-milk or buttermilk, with frequently an addition of peas or beans, or barley meal. Such good keeping not only makes them increase rapidly in size but renders them fit for the butcher at an early age. Swine are sold to the butcher at different ages and under different names, as pigs when a few weeks old as porkers at the age of five or six months and as full grown hogs at from eighteen months to two years old. The young pigs are commonly roasted whole, the porkers are used as fresh or pickled pork, and the full grown hogs for the most part converted into ham and bacon. The demand for porkers, which for London in particular is very great, and which continues almost throughout the year is chiefly supplied from the dairies within reach of that metropolis.

### SECT. IV Curing of Pork and Bacon.

7522. The curing or pickling of pork is carried on to a considerable extent at many of our sea-ports.

7523. The carcasses are cut in pieces, and packed in cases or hke made for the purpose, containing from one to two hundred weight. Salt is dissolved in water till the mixture be strong enough to swim an egg. It is then boiled, and, when cold, poured upon the pork, when the end of the stick is fixed, the article is ready for being sent to market. Howderson, a late writer has given particular directions for the curing of bacon, derived upon a long course of experience, which, therefore, deserves to be more generally known.

7924. The curing of bacon is thus described by Henderson, after much experience —

7925. After the carcass has hung all night, lay it upon a strong table, or bench, upon its back, cut off the head close by the ears, and cut the hinder feet as far below the hough as will not disfigure the hams, and leave plenty of room to hang them by. Then take a cleaving knife, and if necessary a hand saw, and divide the carcass upon the middle of the back-bone, laying it in two equal halves. Then cut the ham from the side by the second joint of the back-bone which will appear on dividing the carcass, then dress the ham, by paring a little off the flank or skinny part, so as to shape it with a half round point, clearing off any top fat that may appear. The curer will next take off the sharp edge along the back-bone with his knife and mallet, and slice off the first rib next the shoulder where he will perceive a bloody vein, which he must take out for if it is left in, that part is apt to spoil. The carcass must be squared off where the ham was cut out.

7926. In killing a number of swine what sides you may have dressed the first day lay upon some flags or boards, putting them up across each other and giving each pile a powdering of saltpetre, and then covering it with salt. Proceed in the same manner with the hams, by themselves, and do not omit giving them a little saltpetre, as it opens the pores of the flesh to receive the salt, and besides, gives the ham a pleasant flavour and makes it more juicy. Let them lie in this state about a week, then turn those on the top undermost, giving them a fresh salting. After lying two or three weeks longer they may be hung up to dry in some chimney or smoke house. Or, if the curer chooses, he may turn them over again without giving them any more salt, in which state they may lie for a month or two without catching any harm, until he has convenience for drying them. Henderson practices for many years the custom of cutting his fitches and hams through the country to farm-houses, and used to hang them in their chimneys and other parts of the house to dry some seasons, to the amount of five hundred carcasses. This plan he soon found was attended with a number of inconveniences, and therefore he invented a smoking house.

7927. Henderson's smoking-house is about twelve feet square, and the walls about seven feet high. One of these huts requires six joists across, one close to each wall, the other four laid sunder at proper distances. To receive five rows of fitches they must be laid on the top of the wall. A piece of wood strong enough to bear the weight of one fitch of bacon must be fixed across the belly end of the fitch, by two strings, as the neck end must hang downwards. The piece of wood must be longer than the fitch is wide, so that each end may rest upon a beam. They may be put so near to each other as not to touch the width of it will hold twenty four fitches in a row and there will be five rows, which will contain one hundred and twenty fitches. As many hams may be hung at the same time above the fitches contrived in the best manner we can. The lower end of the fitches will be within two and a half or three feet of the floor which must be covered five or six inches thick with sawdust, and must be handled at two different sides, it will burn, but not cause any flame to smoke the bacon. The door must be kept close and the hut must have a small hole in the roof so that part of the smoke may ascend. That lot of bacon and hams will be ready to pack up in a hogshead, to send off in eight or ten days, or a little longer if required, with very little loss of weight. After the bacon is salted, it may lie in the salt-house as described until an order is received, then immediately hang it up to dry. Henderson found this smoke-house to be a great saving, not only in the expense and trouble of employing men to cart and hang it through the country but it did not lose nearly so much weight by this process.

7928. In the disposal of bacon, whatever is shipped for the London market, or any other, both bacon and hams, must be packed into a sugar hogshead, or something similar to hold about ten hundred weight. Bacon can only be cured from the middle of September until the middle of April. (Henderson's Treatise on Swine p. 24.)

#### SECT V Diseases of Swine

7929. Swine are subject to various diseases, but according to Lawrence they are not generally doctored.

7930. They are subject he says, to pox or measles, blood striking, staggers, quincy indigestion, catarrh, peripneumonia, and inflammation of the lungs called heavings. When sick, pigs will eat, and they will take medicine in their wash, when they will not eat, there is no help for them. As aperients, clematis, and alteratives, sulphur, antimony and madder are our grand specifics, and they are truly useful. As cordials and tonics, treacle and strong beer in warm wash and good peas and pollard. In the measles, sulphur, &c and, if the patient require it give cordials now and then in staggers, bleeding from ear and perhaps nitre. In catarrh, a warm bed and warm cordial wash and the same in quincy or inflammation of the glands in the throat. If external suppuration appear likely discharge the matter when ripe and dress with tar and brandy or balsam. The heavings or roundness of the lungs in pigs, like the roundness of the liver in lambs, is sometimes found to be hereditary there is no remedy. This disease in pigs is often the consequence of colds from wet lodging, or of lusty feeding in a poor state in a certain stage it is highly inflammatory, and without remedy. Uction with train oil, and the internal use of it, have been sometimes thought beneficial.

#### CHAP. VIII.

Of the Goat, Rabbit, Hare, Dormouse, Deer, and various other Animals, that are or may be subjected to British Agriculture.

7931. The goat (*Capra hircus* L., fig. 905) is a native of many mountainous parts of Europe, Africa, Persia, and India. He is domesticated throughout Europe, feeds on branches of shrubs, on hichens, hemlock, &c. is seldom destitute of horns, of active habits like the deer, treacherous, petulant, roaming, and lascivious. Gravid four months and a half brings from one to two at a birth, and lives ten or twelve years. The female will allow itself to be suckled by the young of various other animals and a foal which has lost its mother has been seen thus nourished by a goat, which, in order to facilitate the process, was placed on a barrel. The attachment between the nurse and foal appeared strong and natural. In its internal structure, it ap-

tremely resembles sheep, but is far superior to them in alertness, swiftness, and intelligence. The goat approaches man without difficulty, is won by kindness, and capable of attachment. The extremely unpleasant odour attending these animals is supposed to be beneficial, and horses appear so much refreshed by it, that a goat is, on this account, often kept in the stables of the grant. It is a singular local peculiarity, that in Angora only, the animals of the *Capra*, *Ovis*, and *Lepus* tribe, have long soft silky hair.

7332. The *Angora goat*, a native of Turkey is chiefly valued for its exquisitely fine hair down, which grows under its coarse hair, and of which the Cashmere shawls are manufactured. The down is obtained by gently combing them. A considerable number of this breed were imported into France from Persia, in 1624, and stationed at St. Omer, with a view to their increase, and the establishment of the shawl manufacture. The kids of this stock are said to be abundantly covered with down and hair, and superior in strength and appearance to indigenous French kids of the same age. It is a common opinion, that the down of this goat degenerates when the animals are removed from the pasturage of Angora. But this is likely in part to arise from the neglect of cleaning and washing them, which at Angora is so assiduously attended to. By a late Report of M. Turmeux to the Paris Agricultural Society the French Angoras have increased in number, and prosper equally with the native variety.

7333. The *Spanish goat* (*Fig 504*) is remarkable for its prodigious ears, and is common throughout the East, in Egypt, and on the coast of Africa. It has likewise been introduced into Sicily, but can only be kept in health in very warm situations.

906

7334. The *Chamois goat* a native of Switzerland, is a species of *Capra*, and will be afterwards noticed.

7335. The *goats of Wales* are generally white, and are both stronger and larger than those of other hilly countries. Their flesh is much used by the inhabitants, and often dried and salted, and substituted for bacon. The skins of the kids are much valued for gloves, and were formerly employed in furniture, when painted with rich colours, of which they are particularly capable, and embellished with ornamental flowers, and works of silver and gold. The goat may be of some advantage in rocky barren countries, where nothing else can get a support for life. They will climb the steepest rocks, and there browse upon briars, heath and shrubs of various kinds which other creatures will not touch of. They will feed on grass in pastures, but, as they love browsing on trees much better great care should be taken to keep them from valuable plantations.

7336. The *produce of the goat*, from which advantage is chiefly obtained, is the milk, which it yields in large quantities, and which is accounted the best milk of all animals. They mix this and cows' milk together in some parts of the kingdom, and a very valuable cheese is made from it. Besides this, the kids or young goats are very fine food, and the best kinds bring flesh two or three at a time, and that twice a year.

7337. *Goat's hair* is also valuable. It may be sheared as the wool from sheep, and is excellent for making ropes that are to be used in the water, as they will last a great while longer than those made in the common way. A sort of stuff is also made of it in some places.

7338. The *skin of the goat* is also in great esteem, and many of the inhabitants of Coernarvonshire kill them merely for the sake of their fat, which makes candles of a superior quality to the common. Of their horns excellent handles are made for tucks and penknives. The skin is peculiarly well adapted for the glove manufactory, especially that of the kid, as it takes a dye better than any other skin. The old skin is also of great use, being preferred to that of the sheep, and the flesh affords a cheap and plentiful provision in the winter months, particularly when the kids are brought to market. The haunches of the goat are frequently salted and dried, and supply all the uses of bacon. Thus by the Welsh is called *cech yr oed*, or hung venison.

7339. The *kind of goats for keeping to advantage* should be chosen in this manner. — The male should have a large body, his hair should be long, and his legs straight and stiff; the neck should be plain and short, the head small and slender the horns large, the eyes prominent, and the beard long. The female should have a large udder, with large teats and no horns, or very small ones. Goats should be kept in flocks, that they may not straggle, and they should have good shelter both in summer and in winter the heat and cold being both prejudicial to them, and coupled in December. They should have no litter in winter but only a paved floor kept clean. The kids are to be brought up for the table in the same manner as our lambs are.

7340. The *Cashmere shawl goat* has been successfully introduced into England, by C. T. Tower Esq. of Weald Hall, Essex. and as that gentleman by this time must have some of his flock to dispose of, we think their introduction among rotagers for their wool, and also, as suggested (*Genl Mag* vol v p. 537), for their milk, a fair subject for some of our female readers to speculate on. This variety of the common goat, or probably it may be a distinct species, is a fine looking animal and would be very ornamental in a park, or a ruin, on the roof of a cottage, or in a churchyard. It would also be very pleasant to have a home-made Cashmere shawl. We shall therefore give all the information we can on the subject from Mr. Tower's account, as published in the last volume XI. I. of the Transactions of the Society of Arts. The Cashmere goat was brought from Persia to France during the time of Napoleon, and under his patronage, by the celebrated M. Turmeux, in 1823. Mr. Tower happening at that time to be in Paris, purchased four of them, two males and two females, and succeeded in conveying them safely to his residence in Essex. The soil of the park at Weald Hall, where they have been kept ever since, is moist, and the situation is much exposed. The animals here, nevertheless, continued in health and multiplied rapidly, so that his present flock consists of twenty-seven, including the four original ones. Of these latter a polled female, which was sold when purchased by him, has every year produced at least one kid, and has twice had twins. These individuals of which the horns crest are in Persia esteemed the best and one of Mr. Tower's last year's kids has this peculiarity. They show no impatience of cold, and are very healthy, requiring only the constant shelter of a shed, in very rough weather. In spring, summer and autumn, they graze like sheep; and during winter have been fed with hay and refuse vegetables from the garden, but their favourite food is greens (*Urtica europæa*) which they devour eagerly without being annoyed by its prickles. They damage young plantations, but not more than other goats or deer will do. They breed very early, three of Mr. Tower's goats this year produced kids before they were themselves a twelvemonth old. A few produce brown wool, but that of far the greater proportion of the goats is white, and this latter is more valuable than the other. The coat is a mixture of long coarse hair, and of short fine wool; this latter begins to be longer early in April, and is collected neatly and expeditiously by combing the animals two or three times, with much a comb as is used for horses' manes. A good deal of the long hair comes off at the same time, but the manufacturer has found no difficulty in separating it. The produce of a male is about four ounces, and of a female about two ounces. Two pounds of wool so it comes off the goat's back may be estimated to make one shawl, fifty four inches square. It will therefore require ten goats, male and female to furnish materials for one shawl. Mr. Tower has this year had three shawls made of his wool,

one of which was examined by the committee of manufacturers. The yarn was spun by Messrs. Pease, of Nottingham, and was proved by Messrs. Miller and Sons, of Falmouth. The Tower's yarn was compared with one made in Scotland, of French short-staple wool, to which it was evidently far superior. It was also compared with a shawl of St. Turpin's own make, and was considered by very competent judges to be superior to this also. (*From the Rev. Rev. vol. xxi. as quoted in Gard. Mag. vol. vi.*)

7941. The rabbit (*Lepus Cuniculus L.*, fig. 907) is indigenous in most temperate climates, but not so far to the north as the hare.

907

7942. In a wild state it forms long winding burrows, keeps its hole by day, feeds morning, evening, and night on vegetables and grain. It is the prey of hawks, badgers, polecats, and caught by ferrets. It breeds thirty days, brings from four to eight young, five, and sometimes as many as seven times a year. The varieties common in Britain are the white, black, variegated, and silver grey. The hare and rabbit are distinguished from each other externally chiefly by the proportional length of the hind legs to that of the back and in the ears of the hare being longer, and those of the rabbit shorter than the head. The burrows of rabbits are called warrens, which are most numerous in the sandy soils

of Norfolk and Cambridgeshire. They sometimes extend to 2000 or 3000 acres, and many have been hitherto considered to pay better in that state than in any other. Arthur Young, however, has shown in his *Survey of Lanesdown*, that though a rabbit warren may afford a high interest on the capital of the occupier, yet the rent it yields to the owner of the soil is less than would ultimately be obtained by planting or breaking up, and laying down with clover or some other suitable herbage plant. In the mean time, as they continue to exist, and are subjected to a kind of management, we shall submit a short outline of it under the heads of extent, soil and situation, fencing, stocking, breeding, rearing, and produce. Afterwards we shall take a view of the mode of managing rabbits in hutches.

7943. The extent of warrens varies from 100 to 3000 acres, but a convenient size is considered to be 1500 or 2000 acres. The soil and situation should be dry sandy, warm, and poor: rich grass or herbage being found to produce a scouring, which sometimes carries off the greater part of the stock. Warrens are generally enclosed with walls either of stone or turf, an essential addition to the latter being a coping of furze, reeds, or stiff straw. Fencing is used in some places, but a brook is found insufficient, as the rabbits have been found to swim across.

7944. Warrens are often stocked by nature, and all that art has to do in that case is to protect the produce, but in some cases they are formed on ground where rabbits do not exist naturally, or where they exist it is considered desirable to change the breed.

7945. In stocking a warren, whether the surface be flat or hilly artificial burrows are sometimes made, to reconduce the rabbits to the ground and to preserve them from vermin, until they have time to make their own burrows. These are bored with an auger of a diameter large enough to make a burrow of a sufficient width. In a level warren, these augers may from time to time, be found useful in forming such holes. They, however, in most cases, are capable of making burrows for themselves. Some warren lands are stocked in the proportion of three couples to an acre, while in others it is in a considerably larger proportion. In Lincolnshire, one buck or male rabbit is said to be sufficient for one hundred does, or females, but this is certainly a much larger proportion than in most other districts. On the wild warrens of Yorkshire according to Marshall, one male is considered sufficient for only six or seven females, and the owner they can be brought to that proportion the greater the stock of young ones that may be expected, it being the nature or economy of the males to destroy their young especially when the proportional number is too great.

7946. The warrens employed as stock for warrens are the common grey and silver grey breeds, the former of which is found to be considerably more hardy and much better for the purpose of food, but the latter has greatly the advantage in the value of the skin. Till lately the common grey rabbit, probably the native wild rabbit of the island, was the only species. At present, the silver haired rabbit is sought after and has, within the last few years, been introduced into most warrens. The skin of the grey rabbit is cut, that is, the wool is pared off the pelt, as a material for hats, whereas, that of the silver haired rabbit is dressed as fur, which, it is said, goes principally to the East Indies. The colour is a black ground, thickly interspersed with single white hairs. The skin of this variety sell for about four shillings a dozen more than those of the common sort, a sufficient inducement for propagating it in preference to the grey breed.

7947. The rabbit begins to breed at an early age, as at eight, ten, or twelve months, going only about thirty days with young, the young being little more than three weeks old before they appear from the burrow, during which time they are suckled twice in the day by the mother. It is, therefore, evident that they may breed seven times in the course of the year under good keep, as the does take the buck almost immediately after producing their young. In warrens that are enclosed it is, however, and that they seldom breed more than two or three times in the year.

7948. The management of a rabbit warren is a very simple business. Birds and beasts of prey are to be kept off by taking them in traps, dogs and cats kept off and rats, moles, mice, and other vermin destroyed if abundant or troublesome. Man himself is to be guarded against in some situations. Additional food is to be supplied in the winter season, when the weather is severe, such as fine green hay, mangel, clover, turnips, and others of the same sort, which must be distributed over the warrens. It is supposed that turnips answer the best in deep mows, as the rabbits can discover them by the scent. This sort of food is given in the quantity of two or three large cartloads to a thousand couples per day and one load of hay in the same time during a storm. It is likewise sometimes the practice to distribute billets of new cut ash boughs, gorse or white, and other similar woods in the warrens, the bark and other parts of which is eaten, by which the proportion of hay is lessened in a considerable degree. In great mows it is necessary to clear it away from the ditches or fences to prevent the rabbits from getting over them.

7949. This sort of stock is mostly taken by nets or traps, set in the form of a fold between the places where they run and those where they feed the rabbits being hunted into them as they return from feeding. Sometimes they are taken by ferrets and terriers. The wild warreners, Marshall says, have three ways of catching their rabbits, with old nets, with spring nets, and with traps, a species trap. The old nets are set about midnight, between the burrows and the feeding grounds, the rabbits being driven in with dogs, and kept enclosed in the fold until morning. But the spring net when used, he believes, generally laid round a haystack or other place where rabbits collect in numbers. It is added, that the trap is a more modern invention. It consists of a large pit or ditch, formed within the ground and covered with a floor, or with one large hollow door, having a small trap-door towards its centre, into which the rabbits are led by a narrow mouth. This trap, on its first introduction, was set mostly by a haystack, hay being at that time the chief winter food of rabbits, or on the outside of the warren wall, where rabbits were observed to scratch much in order to make their escape. Since the cultivation of turnips as a winter food for this species of stock has become a practice, the situation of the trap has, he says, been changed. Turnips being cultivated in an enclosure within the warren, a trap is placed within the wall of this enclosure. For a night or two the mouth is left open and the trap kept covered (with a board or triangular rail, in order to give the rabbits leave to retreat).

7950. The annual produce per acre is rarely estimated at four tons or four to eight or ten couple, yielding a profit of from eight to ten, or even fifteen shillings, where they are conducted under a good

system of management. The produce is the largest on new lands; however, much of the profit must always depend on abundance, so as to be near good markets. These animals are in which is turned down from the end of October to the beginning of January, in which period the best skins are produced; of course a large proportion of them is killed in this short time. The farmer often retains great loss in weight by the purchasers are called half skins, quarter skins, and racks, sixths of which are usually considered as one whole skin. The rabbits are disposed of by the hundred, six score couple being considered as one hundred.

7281. The breeding and rearing of tame rabbits is carried on in hutches or stores of houses placed in fields or apartments of any kind secure from vermin. We shall give a view of the practice as to rabbitry and its structure, variation, breeding, feeding, and produce.

7282. The rabbit-houses should be particularly dry and well ventilated, as these quadrupeds are very subject to also not used to their surroundings like sheep.

7283. The beds or hutches (Fig. 503.) are boxes or chests, eighteen inches or more high, and from two and a half to three feet wide, generally divided in two (a and b), and the recess thus formed communicating by a sliding door (c) the use of which is to confine the rabbits in the inner division (a), whilst the outer (b) is for cleaning. Generally three hutches are placed in rows above each other against one side of the rabbit-house, and sometimes they are placed in the open air against a wall, within a wired or netted enclosure. Sometimes they are ranged round the room, or on stands about three feet high on the floor. In both these cases it is to be understood that they are not allowed to run about the rabbit-rooms, the use of which is solely to enclose and protect them in an atmosphere of moderate temperature, and to contain a bin with corn, a trace of clover hay, and any such food as sheep will live and thrive upon.

along the floor; but the safest mode is to place them on brackets round the room, or on stands about three feet high on the floor. In both these cases it is to be understood that they are not allowed to run about the rabbit-rooms, the use of which is solely to enclose and protect them in an atmosphere of moderate temperature, and to contain a bin with corn, a trace of clover hay, and any such food as sheep will live and thrive upon. The usual feeding rabbits as hatched is simply a trough (c), which may be furnished with water, and hard wood, underneath, or cast iron, as rabbits are very apt to gnaw them; it should be divided on the surface crossways every four or six inches, to prevent them from scratching and throwing out their corn. Some add a small rack for their clover, but that will not be lost if given on the floor in small quantities.

7284. The rabbits of the *Laguna* breed yield in Normandy a wool which serves as a primary material in several considerable manufactures. It is used also mixed up with sheep's wool and cotton. The rabbits are found to delight more than any thing in the leaves of the Robinia wood-chestnut, and as this plant grows on common sandy soils it has been proposed to cultivate it for the sake of these rabbits. (Cott. to Board of Ag. vol. I. p. 225.)

7285. There are numerous varieties of tame rabbits, but the broad-chested and short-legged are the most hardy and fetch most expeditiously. There is a large variety of the hare colour which has high-coloured and high-favoured flesh, were never; then out of the common rabbit, they make a good dish cooked like the hare, which at six or eight months old they nearly equal in size. The large white and yellow and white species have whiter and more delicate flesh, and cooked in the same way will rival the turkey. The Turkish or French rabbit is esteemed by some, but differs little from the common variety. All these and other varieties are to be had from the London dealers and poultrymen.

7286. Breeding. The doe will breed at the age of six months and her period of gestation is thirty or thirty-one days. It should be provided that the buck and doe are by no means to be left together, but their union having been successful, the buck must be immediately withdrawn, and the doe bred again in three days; in fact, with rabbits this business is conducted on the same principle as in the stud. Like chickens, the best breeding rabbits are those kindled in March. Some days before parturition or kindling, hay is to be given to the doe, to assist in making her bed with the flus which nature has instructed her to tear from her body for that purpose. She will be at this period seen sitting upon her haunches and tearing off the flus, and the boy being presented to her, she will with her teeth reduce and gnaw it to her purpose. Biting down of the litter or bed is the first sign of pregnancy. The number produced generally between five and ten; and it is most advantageous always to destroy the weak or sickly ones as soon as their defects can be perceived; because five healthy and well grown rabbits are worth more than double the number of an opposite description, and the doe will be far less exhausted. She will admit the buck again with profit at the end of six weeks, when the young may be separated from her and weaned, or the young may be suckled two months, the doe taken back at the end of five weeks, so that the former litter will leave her about a week before her next parturition. A notion was formerly prevalent of the necessity for giving the buck immediately after the doe had brought forth, but she should pine, and that no time should be lost; and if it were intended that no time might be lost in destroying the doe, such indeed would be the most successful method. Great care should be taken that the doe, during her gestation, be not approached by the buck, or indeed by any other rabbit; or from being harassed about, she will almost certainly cast her young. One doe in a thousand may devour her young, the sign that she ought to be otherwise disposed of. Some does admit the buck with difficulty, although often apparently in season, such should be immediately stifened off; since it can never be worth while to keep any individual for breeding if a stock to be produced in such multitudes against which there is an objection. Should the doe be weak on her bringing forth from cold, cough, or other causes, she will drink beer-candle as well as any other lady; or warm fresh grubs will comfort her, a salt mash, scalded fine pollard, or barley-meat, in which may be mixed a small quantity of scented horse hair. With due attention to keeping them warm and comfortable, and guarding against every sudden impression from cold, and more particularly moist air, and with the aid of the best and most nourishing food, rabbits may be bred throughout the winter with nearly equal success as in the summer season; but in truth their produce is so multitudinous that one might well be satisfied with four or five litters during the best part of the year, giving the doe a winter fallow.

7287. Feeding. According to Mowbray it is better to feed three times than twice a day. The art of feeding rabbits with safety and advantage is, always to give the upper hand to dry and substantial food. Their nature is congenial with that of sheep, and the same kind of food, with little variation, agrees with both. All weeds and the refuse of vegetation should be hatched from rabbit-feeding. Such articles are too watery and starchy, and can never be worth attention whilst the more solid and nutritious productions of the field may be obtained in much plenty and will return so much greater profit. Rabbits may indeed be kept, and even fattened, upon roots, good green manure, and hay; but they will pay for corn, and this may be taken as a general rule. Rabbits which have as much corn as they will eat can never take any harm from being indulged with almost an equal portion of good substantial vegetables. However the test of health is that their dung be not too moist. Many at most of the town fashions never allow dry greens at all; the reason, I suppose, because they find almost misery on grains. The corn proper for rabbits is oats, peas, wheat, rye, and some give buckwheat; the greens and roots fit to eat as our cattle from turneps, cabbages, Jerusalem artichokes, and if potatoes, boiled or steamed; because, cabbages leaves, clover leaves, ferns. Mowbray has had them sown from ending rape, and not imperceptibly feed best might have a similar effect. The best dried herbage is clover and meadow hay and pea and bean straw.

7288. Rabbits are generally cold from the neck, but there is also a demand for those of larger size, which may be fattened upon corn and hay with an allowance of the best vegetation. The better the food, the

greater weight, better quality and more profit, which is generally the case in the feeding of all animals, some taken with grain and pollard. However, wheat and pulse are expensive, but could find no difference in the produce of these feeds. The rabbit's flesh being dry, the absence of perfumed greens may tend to render it more juicy; and probably the old complaint of the dryness of the flesh to be cured, entirely fed with hay might be remedied in the same way. Rabbits are so perfection for feeding at the fourth or sixth month beyond which period their flesh becomes more dry and somewhat hard. It requires three months, or nearly so, to make a rabbit thoroughly fat and ripe; half the time will make them eatable, but by no means equal in the quality of the flesh. They may not be ever fatted, as appears by specimens exhibited a few years since at Lord Somerville's show which were loaded with fat, without and within, like the best-feeding sheep.

7320. The flesh of the rabbit is esteemed equally digestible as that of fowls, and equally proper for the table of the invalid.

7321. Castrated rabbits might be fattened, no doubt, to the weight of upwards of ten pounds, at six or seven months old. It is said to be successfully practiced in Sussex, near Chichester where on the average not one in three hundred is lost by the operation, which is performed at five or six weeks old. With respect to the quantity of corn consumed in fattening, a young buck which weighed three pounds, fit for the spit, was put up in good case in August, and was only one month in feeding, consuming not quite four quarts of oats, with hay cabbage, lucerne, and clover. The skin, silver and black, worth four pence.

7321. In slaughtering full-grown rabbits after the usual stroke upon the neck, the throat should be perforated upwards towards the jaws with a small-pointed knife, in order that the blood may be evacuated, which would otherwise settle in the head and neck. It is an abomination to kill poultry by the slow and torturing method of bleeding to death hung up by the heels, the veins of the mouth being cut. But still more so the rabbit, which in that situation emits horrible screams. The entrails of the rabbit, whilst fresh, are said to be good food for fish, being thrown into ponds.

7322. The rabbit is a voracious animal, and equally fond with the cat of the head being stroked at the same time it is not destitute of courage. A whimsical lady admitted a buck rabbit into her house when he became her companion for upwards of a twelvemonth. He soon intimidated the largest cats so much, by chasing them round the room and darting upon them, and tearing off their hair by mouthfuls, that they very seldom dared to approach. He slept in the lap by choice, on top of a chair or the hearth rug, and was as full of mischief and tricks as a monkey. He destroyed all the rush-bottomed chairs within his reach and would refuse nothing to eat or drink which was eaten or drank by any other member of the family.

7323. Diseases. No live stock is less liable to disease than the rabbit, with regular and careful attention, such as has been pointed out so that any accident and accidental disorder is less and most cheaply remedied by a stroke behind the ears. But waste of care must be rewarded, if at all, by an opposite conduct, and improper food exchanged for its contrary. Thus, if rabbits become pot-bellied, in the common phrase, from being fed on loose vegetable trash, they must be cured by good hard hay and corn ground malt or peas, or any substantial or absorbent food. Their common liver complaints are incurable, and when such are put up to fatten, there is a certain exterior to be observed. They will not bear to be pushed beyond a moderate degree of fatness, and should be taken in time, as they are liable to drop off suddenly. The dropsey and rot must be prevented, as they are generally incurable nor is a rabbit worth the time and pains of a probable cure.

7364. The hare (*Lepus timidus* L. fig 910.), if taken young may be tamed and domesticated, and has occasionally been nursed by a cat. Sonnum the naturalist, and Cowper the poet, had hares in a complete state of domestication. As the fur of this animal is of greater value for hat-making than that of the rabbit, it would be a very desirable circumstance if it could be substituted for that animal in warrens. Its flesh would certainly be

deemed preferable, and in general it is a large animal. It lives on the same sort of food as the rabbit, produces generally three young ones at a time, and breeds at least three times in a year. It is not improbable that in some situations, where the soil is dry and poor, a hare warren or pack might be found to answer, the price in the metropolis being never less than ten times that of rabbits.

7365. There is a hare warren near Banstead Downs it contains about three acres of ground. 220 brace are usually kept in it. They are fed in the summer on clover, rape, &c. and in the winter on hay. The warren is surrounded by a brick wall about ten feet high, with openings at regular distances, within which are wire gratings on hinges these give way to the hares, when they enter the warren and they are so constructed, that they immediately close after them, and so prevent their escape.

7366. The Guinea pig, or restless Cavy (*Cavia Cobaya* L. fig 911), is a native of Brazil, but domesticated in Europe, and treated and used like the tame rabbit. In Italy, the flesh is considered a delicacy, and the skins are nearly as valuable as those of rabbits.

7367. The Guinea pig is one of the most prolific of animals, and Buffon calculates that in twelve months only 1000 might be produced from a single pair as the female has been known to bring forth young when two months old only the time of gestation is only three weeks and she will produce at least every two months. The young are six or seven months before they arrive at their maturity of growth, but within the short period of twelve hours from their birth are nearly as alert and active as those fully grown, and therefore require parental custody only for a little time. Vegetables form their food and on a great variety of these they will scurrah and scamper. They drink but little, appear after eating to ruminate, and are extremely apt to be affected by cold. They are uncommonly clean in their habitations, and are often to be seen smoothing and shining their fur with particular attention and perseverance.

7368. The fat dormouse (*Myoxus Glis* L.) is a native of the woods of Germany and Russia; and has a good deal of the habits of the squirrel. It feeds on fruit, lays up a winter store, forms its nest in hollow trees, sleeps by day and grows very fat in autumn.

It was cultivated by the Romans, and highly prized by them as food. The body is six inches long.

7369. *Of the deer* (*Cervus L.*) there are three species in cultivation in this country: the stag, roe, and fallow deer. The latter are now almost exclusively cultivated in parks, as articles of luxury, and, it is conceived, might answer to a small extent in husbandry.

7370. The stag (*C. Elaphus L., Ag. 912. a*) is found in nearly all the temperate climates of Europe and

912

Asia. It is also found in North America, but attains its largest size in Siberia. From the branches of its antlers, the elegance of its form and movements, and the strength of its limbs, it deservedly attracts particular admiration, and may be regarded as a principal embellishment of the forest. The stag is remarkable for a fine eye, and an acute sense of smelling. His ear also is exceedingly sensitive, and several sounds appear to possess over him the power of exciting complacency if not rapture. He seldom not unfrequently employs the shepherd's pipe to daisy him to his destruction; and Playford, in his *Introduction to Manx*, states that he once met a herd of twenty stags near Koyston, which readily followed the tones of a violin and harp, played by their conductors, but stopped whenever the music was suspended. Their whole progress from Yorkshire to Hampton Court was attended and it was supposed extremely facilitated, by these sounds. The stag is simple and unassuming, and employs no arts to avoid detection or pursuit, until after having received considerable molestation. His food consists in winter of moss and bark; in spring, of the catkins of willow and hazel, and the flowers and buds of cornel; in summer of the grain of rye, and the tender shoots of the alder; in autumn, of the leaves of brambles, and the flowers of hawthorn and hawthorn. He eats with slowness, and ruminate with some considerable effort, in consequence of the distance between the first stomach and the mouth. In March, generally he sheds his antlers, which are not completely renewed till August. He will live to between thirty and forty years of age, and was formerly mistaken the other vulgar error of antiquity supposed capable of attaining most extraordinary duration. The stag is supposed to have been introduced from France into England, where he has lately been made to give way to the fallow deer as an animal more gentle in its manners, and more valuable as food. In some parts of Scotland he is yet to be found in his original wild state. A stag of five years old is, in hunting, termed a hart; the female, does; and the young, fawns.

7371. The roe (*C. Capreolus L., Ag. 912. b*) is the smallest of the deer tribes which are natives of Europe. It is generally of a reddish brown colour; graceful, sprightly and courageous, particularly cleanly and delighting in dry and mountainous situations. It leaves a strong scent behind it, but possesses such arts of defence, that by various doublings and intermixtures of past with present emanations from its body it frequently baffles the most experienced dogs, and remains in a state of security, while the full pack passes almost close by its retreat, distinguishing it neither by sight nor smell. It differs from the stag in the consistency of its attachment, and the parents and their young constitute a family, never associating with strangers; two fawns are generally produced by the female at a birth, one of each sex, which, living together, form a mutual and inviolable attachment. When a new family is to be reared, the former is driven off to provide for itself, but returns again after a certain interval to the mother, whose former attention is restored. A final separation speedily takes place however soon after this return, between the fawns of the season preceding the last and their dams, and the former remove to a distance, constituting a distinct establishment, and rearing an offspring of their own. When the female is about to bring forth, she selects herself in some remote recess of the forest, from which she returns at the end of about ten days with her fawns, just able slowly and weakly to follow her steps. In cases of danger she hides them in a place deemed by her most secure from the keenness and attracts the attention of the latter from them to herself; hungry, by her own perils or even destruction, to effect the security of her offspring. In winter, these animals feed on mosses, bracken, heath, and gullies; and in spring they eat the young wood and leaves of almost every species of tree, and are said to be so affected, as if with intemperance, by the fermentation of the food in their stomachs, that they will approach men and other enemies (whom they generally shun with great care) without apprehension or suspicion. The flesh of these animals is excellent, though after two years of age that of the males is stiffest and toughest. The roe exists now in no part of Ireland, and, in Great Britain, only in a few districts of the Highlands.

7372. The fallow deer (*C. Elanus L., Ag. 912. c*) is in general much smaller than the stag; but he Spain is nearly equally large. In France and Germany it is rarely to be found, and it has never been known to have existed in America. It has the elegance of the stag, unaccompanied with a much more tractable disposition. It sheds its antlers, which, as in the stag species, are peculiar to the male, every year; it is stated to live to the age of twenty years, and arrives at its maturity in three; it is by no means fiducious in its food.

7373. *Deer husbandry.* The author of the *Agricultural Survey of the County of Hertford* observes, that "the End of October, justly considering that there is no more propriety in converting an animal to profit than another, makes them an object of husbandry. As soon as the rutting season is over, or usually about the 25th of November his lordship collects from the hand the week once, some of which would probably die in the winter, and keeps them in a small park that has a shed on one side, and a net over the whole against the wind, the net very warm, and well shrouded. Their antlers are inclosed in a sack, the sides in well flannel, and their feet in a very small capsule on pins, three by three, which prevents up for the want of better feed. At three, during the winter they have clover, hay cut into chaff, and if they do not eat it well, a little salt is added. They have always plenty of water and are

kept perfectly clean: much attention should, he says, be paid by the keeper to keep himself familiar with them, that he may enter the place without disturbing them. The first week, in March he gives them oil-cake, about half a cask each a day, with chaff, wheat straw, &c. as usual; but all are gone in May. Before killing they have some green meat given, to take away any ill humours from the meat, supposing such to be the effect of the feed; for it is certain that the venison is exceedingly good. As to the deer, a haunch actually weighs about 25 pounds; a brace is sold for 15 guineas; the doe, worth 2l. 2s., is the keeper's property, so that the value of a brace amounts to 17l. 7s. exclusive of some trifling articles. The purchaser sends for them." It is added, that his landship usually takes nine hares, his whole winter stock runs to 250 head, in a park of 250 acres, but much of it is chiefly covered with timber; thirty sheep and ten cows also feed on it. The park consumption of hay amounts to thirty-two loads, being retained to that quantity by the use of much leysure, all oak, elm, and Scotch pine being brought for that purpose before felling, which not only saves hay, but improves the flavour of the venison.

7574. By castrating the males of deer when newly dropped, which is not in the least dangerous, it affords the means of having good venison until Christmas, without any other sort of feed than the common grass; they also submit more quickly; the operation must, however, be performed while they are quite young. (*Devonshire Report*.)

7575. The moose deer, or elk (*Cervus Alces L.*), is indigenous in Europe, America, and Asia, as far as Japan, and was formerly wild in this country, though now extinct. It is of the size of a horse—gentle, except when teased by the gad-fly—feeds on twigs and branches of trees, and marsh plants, goes on its hoofs with a shambling gait at the rate of fifty miles a day—has a skin so hard as almost to resist a musket ball, but flesh tender and good. This animal might be introduced as an inhabitant of parks, where it would add to the variety of animated woody scenery and of venison.

7576. The rein deer (*Cervus Tarandus L.*, fig. 913) is an inhabitant of the alpine mountains of America, Europe, and Asia, and is too remarkable an animal, and too well known, to require a particular description or account of his habits.

7577. The same variety have been introduced more than once into the country by the Hon. Daines Barrington, Dal-look, and others, but cannot be kept in parks on account of the want of their particular food. As this lichen abounds on several mountains in Yorkshire, and on many in Scotland and Ireland, some patriotic and curious noblemen might attempt its cultivation. The milk and cream, as Dr. Clarke states, are most excellent, and also the flesh; and even as an article of profit, the sale of the animals as breeding stock would pay for a time. Lichen hay might no doubt be imported at an easy rate from the gulf of Bothnia, and the animal by degrees in the course of a few generations might be habituated to grass or the spray of trees.

7578. The antelope (*Antelope L.*) is a beautiful and numerous genus of animals, partaking of the nature of the goat and deer. Two species, the *A. Salsa*, or scythian, and the *A. Rupicapra* or chamois, are natives of Europe, but the rest of hot climates.

7579. *Antelope*, Pennant observes, are animals generally of a most elegant and active make, of a restless and timid disposition—extremely watchful, of great vivacity remarkably swift and agile, and most of their bounding so light and elastic as to strike the spectator with astonishment. Whilst in very singular they will stop in the midst of their course, gaze for a moment at their pursuers, and then resume their flight. As the chase of these animals is a favourite amusement with the Eastern nations, from that may be collected proofs of their rapid speed. One of the highest compliments that can be paid to female beauty in the Eastern regions is, *like an antelope*. You have the eyes of an antelope. Some species of antelopes form herds of two or three thousand, while others keep in troops of five or six. They generally reside in hilly countries, though some inhabit plains. They often browse like the goat, and feed on the tender shoots of trees, which give their flesh an excellent flavour.

7580. The common antelope (*A. Cervicapra L.*) abounds in Barbary, and in all the northern parts of Africa. It is somewhat less than the fallow deer: its horns are about sixteen inches long, surrounded with prominent rings almost to the top, where they are twelve inches distant from point to point. The horns are remarkable for a beautiful double barbed, which gives them the appearance of the tyre of the axonets. The colour of the hair on the back is brown, mixed with red—the belly and inside of the thighs white and the tail short.

7581. The chamois antelope (*A. Rupicapra*, fig. 914 a) was formerly considered as belonging to the genus *Ovis*, and is generally called the chamois goat. It is found on the mountains of Switzerland, where it is very shy, and hunted both for its flesh and skin. (542.)

7582. The European antelope (*A. Salsa L.*) bears a good deal of resemblance to the common goat, and is as shy or easily scared. They are found in numerous flocks on the banks of Baykhet and other parts of Russia, where they are valued both for the flesh and their skin, which is equal to that of the chamois for gloves.

7583. The alpine, or white-footed antelope (*A. alpin L.*, fig. 914 b), is a large and beautiful species, known only within the space of a few years past. It is said to have been com-

mon to the top of the shoulders; its length, from the bottom of the neck to the base of the tail, four feet; and the colour a fine dark grey. The alpine has of late years been often imported into Europe, and has bred in England. In confinement, it is generally pretty gentle, but is sometimes seized by the or shagreen region, when it will attack with great violence the object of its displeasure. The alpine is said to go

with propagation nine months, and to produce sometimes two at a birth; the young is of the colour of a sheep. There are and various other species of antelopes might probably be acclimated and introduced in great numbers of luxury. The cultivator who first succeeded in breeding them would find no ample recompense at his own price if they happened to come in vogue.

7384. The camel (*Camelus L.*) is a genus of which there are several species, three of which, the dromedary, or Arabian camel (*Ag 915*) the Bactrian camel, and the lama or Peruvian sheep, might certainly be partially acclimated in England, as the first is in Italy (397). They live upon a very little of the coarsest herbage, might have a warm house well littered to retire to in winter, or in cold nights, and would form a singular ornament to park scenery. Besides their hair and skin are valuable, and they might be sold perhaps to romantic travellers or cavalier quacks.

7386. The lama (*Camelus Glama L., Ag 916.*) is the camel of South America and appears to hold a middle place between the sheep, deer, and camel.

7387. Before the entrance of the Spaniards, lamas were the only beasts of burden known to the South Americans. Like camels, they travel slowly but are persevering, tractable and very sure-footed. Since the introduction of mules, they are much less cultivated; but before they were depended on to carry the ore dug out of the rich mines of Potosi. The lama is furnished as the camel with ability to abstain from water by keeping a quantity in its second stomach. Like the camel, its feet also divide, and spread, but by no means equal to those of the camel. It is also furnished with a singular protuberance or spur behind, which enables it the better to lay hold on the ground. The lamas are of various colours, and some of them are smooth and others rough. The height of the lama is about four feet, and its length from the neck to the tail about six feet. It has a capacity of throwing out the saliva to a considerable distance, but which is not possessed of any acid quality.

7388. The camelopard (*Camelopardalis Griffin L.*) a most singular and noble animal seventeen feet high, and as tame and gentle as the camel, might also be naturalised. It lives on the green spray of trees and grass, and frequents forests.

7389. The elephant, rhinoceros, musk ox and a variety of other exotic domestics, might be so far acclimated as to live in Britain as they do in the *Jardins des Plantes* at Paris, viz., with an enclosure for each sort, and a lodge or house for protection in winter or during inclement weather. Were as much attention paid to acclimating foreign animals as there is directed to the same branch of culture in plants, we should soon possess a rich Fauna and the public taste may in time take this direction.

7390. In acclimating the more tender animals, it might be desirable to rear a few generations, first in the south of Italy or in Spain, next in France, and afterwards in the south of England. But the camel, musk ox, zebra, quagga, and antelope might be had at once from the acclimated stock in Italy.

7391. The dog (*Canis familiaris*) is an animal of universal utility and interest. From the earliest ages he has been the companion and assistant of the herdsman, and without his aid the flocks must have been confined to narrow limits, and consequently their propagation would have been greatly lessened. But hardy and bold, he watched by night, and toiled by day securing his charge from the human thief, or the ravenous predatory beasts in the one, and collecting and organising their march during the other. Without the dog, sheep-farmers of the present day would be often at a loss to restrain the wanderings of their flocks; nor is he less useful in guarding the yard by nightly watchings.

7392. The genus *Canis* includes other animals, as the wolf, the fox, the jackal, and the hyena, and many naturalists have regarded our subject, the dog, to be only a mixed animal, originating from the union of some of them. Such is the opinion of Gaidemont, Pallas, and Temminck; while the higher names of Blainvillier and Cuvier are ranged among those who assign him a distinct and specific origin. Blainvillier, who has long extensively investigated the genus of the dog, has bestowed much research on this point; and appears clearly to have traced the dog through his numerous varieties, to a specific origin; but whether originating from a specific or a spurious source, the dog has descended down into such innumerable varieties, that a detail of the forms and properties of them, as they appear among us only, would be utterly hopeless. The results as well as the histories of men have however laid hold on some of these varieties, and have fixed them into permanences, by confining the sexual intercourse to their congeners alone; and of this number there are no less than forty. It would be unnecessary to draw the character of the dog as stated at length by Linnaeus and others: the outlines are the same in all.

7305. The shepherd's dog, in an agricultural point of view ranks foremost among the numerous varieties; indeed, the fanciful notion exists that the father of the whole race of dogs. But did no other variety arise, an inseparable one would be found in the opposite characters which different breeds of this dog possess. Few animals can be more unlike than the small sheep-dog of the Highlands of Scotland and the monstrous drover's dog of Smithfield.

7306. The English sheep-dog (Fig. 917) is usually larger than the northern, is longer on the legs, and has been so long accustomed to have the tail taken off nearly close to the rump, that in some instances the custom has operated on nature; and these dogs are sometimes pupped tailless. The shepherd's dog is not, however usually bred so large as the real cattle or drover's dog but is yet sufficiently strong and fierce. Their colour is in general black and white with half-pricked ears they are extremely docile and intelligent, and seem almost to understand the looks of the shepherd. Some of them are smooth-coated, but by far the greater number are rough and have their hair crisped, which enables them better to bear the effects of continued exposure. The dog very erroneously described by minor naturalists as the cow dog is nothing more than the shepherd's dog, confined principally to the operations of the farm; and often bred taller and either smooth or rough, according to circumstances. The

very soon our destroyers all individuality of breed it being applied to characterise any dog of spurious origin neither in these farm-yard dogs is any characteristic difference whatever observed in fur, qualities, or uses. When the sheep-dog is generally employed in watching the farm-yard, he becomes more fierce and active he accommodates his power to the particular circumstances required of him he knows every field, and every beast, and keeps the whole in subjection. His bite is keen, and principally directed at the heads of cattle, by which he keeps himself safe, and does not injure them.

7307. The sheep-dogs of Scotland are varied in form and size (Fig. 918 and 919) but are all of them usually smaller than those in use in England they are, nevertheless, without competitors in sagacity and excellence. Their general characters are, ears partially upright, head rather pointed, shaggy coat, and a remarkable viscosity or firmness of tail beneath. Immense flocks of sheep may be seen ranging the wilds, without other control save the shepherd and his dog, which receives his commands, executes them, and then waits for further instructions or he often acts with great judgment and promptitude from the impulses of his own sagacity. In which, perhaps, these dogs never shine more than in their readiness to distinguish

the individuals of their own flocks, and their adroitness in keeping out intruders. In driving a number of sheep to any distance a well trained dog never fails to confine the sheep to the road he watches every avenue that leads from it, where he takes his stand, threatening every delinquent and pursuing the stragglers, forcing them into the ranks without doing them any injury. If the herdsmen be at any time absent, he rests satisfied, knowing his dog will not abandon his charge, but will keep them together; and the moment he returns, the sagacious animal gives up his trust, or conducts them to his master according to the word or signal given.

7308. The mastiff or guard (Fig. 920) is a noble animal derived from the Dens; but by selection and cultivation is rendered thicker and heavier though less tall than his original. The powers of this dog are immense, and as a guard he is unrivalled; having the ferocity of a tiger to a stranger with the gentleness of a lamb towards those he knows. His sagacity in detecting the attempts of robbers, and his fidelity in rendering all their bribes, are such, that it is to be lamented his breed has given place in that of the Newfoundland dog, whose qualities as a guard are certainly not equal to his. The mastiff is characterised by small pendulous ears, smooth coat, colour various, often reddish or brindled. The lips are pendulous, jaws of immense strength, but seldom under hung, and his general form is symmetrical for strength.

7309. The bull-dog can be otherwise be considered as connected with agriculture than as he is too often used in the disgraceful and inhuman sport of bull-baiting and however we may admire his invincible fortitude, and his contempt of pain and danger, we must allow him to be the most useless among the dog species. In his attack on cattle he always aims at the front, and generally sustains on the upper lip, where he will hang in spite of every effort of the animal to disengage himself.

7310. The terrier (Fig. 921) is a dog of very great utility and of very varied form and size. His qualities have gained him the greatest care in selection, training and continuing the numerous distinct breeds we witness. The principal varieties may be reduced into the rough and the smooth breeds. The rough breed is originally derived from Scotland, where it is still preserved in a few families in its original purity. These specimens are seldom large, but are exceedingly rough and shaggy in their hair, which is much crisped and brindled. The rough breed in England has become larger and is very often seen white. When mixed with the bull breed, this terrier becomes fierce, much inclined to combat, and forms an excellent guard. The smooth breed produces endless varieties; the principal of which is an elegant black animal with tan markings. A second variety is of varied colours, smaller choler and lower, and is used for earthing foxes, badger-baiting, and vermin killing in general.

For rabbit hunting a very-legged breed is in considerable request. Although particular varieties are often appropriated to particular purposes, yet all have a common property which renders them invaluable to the agriculturist; which is their determined hostility to those animals termed vermin, as foxes, otters, badgers, polecats, with rats and mice. To attack the farmer, they are bred strong, and have a portion of the bull breed in them. For the latter their hardihood activity and looseness of gripe are particularly studied, in which the middle-sized breeds are frequently found to excel.

7311. The pointer setter and spaniel (Fig. 922) it might seem at the first view unnecessary to introduce to the notice of the agriculturist; but a little examination will show that they may be made an object of considerable importance to the farmer. Few dogs command such prices as sporting dogs; and few persons have such opportunities of rearing them so cheaply or so well, as farmers. Many farmers shoot game; most of them do it more or less and it would be very easy to make two hares of pointers or setters, with one or two brace of spaniels, pay a considerable part of the rent of the farm, without other expense than skins, milk and potatoes, or occasionally a little barley meal. We will suppose that a farm has on it three pointer bitches, and one pointer dog, all of acknowledged excellence, and two out of the three bitches may be expected to go to bed early and to produce progeny between the seasons of shooting, when they are wanted from these four brace of pointers may be served, and by continually following the servants and their master they will become so handy that their breaking may be effected

ing the points between this and the next autumn they may be studied and practised in teaching their game, &c., as directed in good sporting works. At the commencement of the following season, if they have been well attended to, although only fifteen months old, the whole may be sold to the London or country dealers, to average six or seven guineas each. or if sold privately they will fetch from eight to twelve and fifteen guineas each, out of which, perhaps, not more than half a guinea can fairly be deducted for keep, &c. The trouble occasioned to the master will be trifling, because connected with a pleasing employ to him as a sportsman, and who will thus have his own sporters for nothing.

7400 *Setters*, as soon valuable, will fetch a higher price but they do not always command so ready a sale, and are more troublesome to break.

7401 *Spaniels* are commonly thought, but most erroneously, almost to break themselves. A really well broke spaniel, however, is so rare, that instead of being worth two or three guineas, which is the usual price it will fetch from five to ten pounds. It would be even less difficult to the farmer to rear spaniels than pointers and by following him continually about the grounds they might be taught perfect obedience, and close rangings, which are the grand requisites, without trouble or expense. In this way four or five brace might be easily brought every season to market, and would always command a ready sale, and a price according to the perfection of their breaking.

7402 *In the breeding and rearing of dogs* for the above purposes, it is necessary to observe the greatest care in their original selection that the breed be of the very best, and one which as it were breaks itself, for it shows the purity of the breed. It is likewise no less necessary that the breed be carefully preserved so to do which, the moment the dogs begin to smell at a bitch, shut her and the intended male closely up, in a confinement inaccessible to other dogs, and there let them remain a fortnight. It is likewise equally necessary, that the dogs peculiarly appropriated to agriculture, particularly the shepherd's dog, should be bred as pure for an animal more liable to sport into varieties. No crossing can on any account be permitted but choice may be made among families of the same variety. In the rearing of this dog, his education should be early and carefully attended to, to make him hardy and familiar with all the signs of the shepherd, who ought himself to be equal to the regular education of his own dog.

7403 *The diseases of dogs* are very numerous. The following are described by Blane as the most prevalent, with their methods of cure.

7404 *The canker* seldom is hardly ever observed to attack any but either old dogs, or those who, by confinement, too full living, and want of exercise, may be supposed to have become diseased by these deviations from a state of nature. It is hardly possible to keep a dog very fat for any great length of time, without bringing it on. This complaint is frequently confounded with the cough that proceeds and accompanies distemper, but it may be readily distinguished from this by an attention to circumstances, as the age of the animal, its not affecting the general health, not producing immediate emaciation, and its less readily giving way to medicine.

7405 *The cure* is often very difficult, because the disease has in general been long neglected before it is sufficiently noticed by the owners. As it is usually brought on by confinement, too much warmth, and over-feeding, as it is evident the cure must be begun by a steady persevering abstinence in these particulars. The medicines most useful are alteratives, and of these occasional emetics are the best. One grain of tartarized antimony (i. e. tartar emetic), with two, three, or four grains of calomel, is a very useful and valuable emetic. This dose is sufficient for a small dog, and may be repeated twice a week with great success, — always with palliation.

7406 *Of diseases of the eyes*, dogs are subject to almost as great a variety as ourselves, many of which end in blindness. No treatment yet discovered will remove or prevent this complaint.

7407 *Scars eyes*, though not in general ending in blindness, is very common among dogs. It is an affection of the eyelids, is not unlike the scrofulous affection of the human eyelids, and is equally benefited by the same treatment. An elegant made of equal parts of nitrated quacksilver ointment, prepared tutty and lard, very lightly applied. Dripping of the eyeball is likewise sometimes met with, but is incurable.

7408 *Cancer*. The violent, dreadful ulcer that is so fatal in the human subject and is called cancer, is unknown in dogs, yet there is very commonly a large scirrhous swelling of the teats in bitches, and of the testicles (though less frequent) in dogs, that as it sometimes becomes ulcerated, so it may be characterized by this name. In the early state of the disease dissections prove useful, as vinegar with salt, and camphor and Spanish flies, with mercurial ointment, have sometimes succeeded. Taking care to avoid irritating the part so much as to produce salivary. But when the swelling is detached from the belly and hangs pendulous in the skin, it had better be removed, and as a future preventive suffer the bitch to breed. Scirrhous testicles are likewise sometimes met with; for these no treatment yet discovered succeeds but the removal of the part, and that before the spermatic chord becomes much affected, or it will be useless.

7409 *Colic*. Dogs are subject to two kinds of colic; one arising from constipation of the bowels, the other is of a kind peculiar to dogs, apparently purking of the nature of rheumatism, and also of spasms. From a sudden or violent exposure to cold, dogs become sometimes suddenly paralytic, particularly in the hinder parts, having great tenderness and pain, and every appearance of lameness. In every instance of this kind, there is considerable affection of the bowels, generally constipation, always great pain. A warm bath, external stimulants, but more particularly active aperients, remove the colic. Colic arising from constipation is not in general violently acute from the pain it produces sensation, however, it appears accompanied with intense spasms that is immediately dependent on the confinement of the bowels. In the former colic active aperients, as castor oil with yll. doctine, i. e. silex oil and glyster. In the latter make oil with turpentine and other.

7410 *Cough*. Two kinds of cough are common among dogs, one accompanying distemper, the other is an asthmatic affection of the chest. (See 7404, 7411.)

7411 *Distemper*. This is by far the most common and most fatal among the diseases of dogs; hardly any young dog escapes it; and of the few who do escape it in their youth, three fourths are attacked with it at some period afterwards: it is long a mistake that young dogs only have it. It, however, generally

which dogs, which he says is neither a shark nor a scull, but a pure composition of both. It has been told by some that this disease is contracted by heat or bad food, and by others that it never arises from any other cause than the bite. Accordingly this disease is rare in the southern parts of Europe, more common in the southern provinces of that empire, and totally unknown under the burning sky of Egypt. At Aleppo, where these animals perish in great numbers, the want of water and food, and by the heat of the climate, this disease was never known. In other parts of Asia, and in the hottest zone of America, dogs are never attacked with madness. Blaine knows of no instance of the complaint being cured, although he has tried, to their fullest extent, the popular remedies of profuse bleedings, strong mercurial and arsenical doses, vinegar, opium, decoctions, leeches, blisters, water plants, &c.; he therefore recommends the attention to be principally directed towards the prevention of the malady.

744. The preventive treatment of rabies or madness in, according to Blaine, always on many occasions in the human subject, from the immediate part bitten being usually destroyed; in which case the removal of the part by amputation or cautery is an additional remedy. But, unfortunately for the agriculturist, it is not easy to detect the bitten parts in cattle, nor in dogs, and it would be therefore most desirable if a certain infallible preventive were generally known. Dr. Mead's powder the Chondrich powder, sea-bathing, and many other nostrums are deservedly in dispute; while a few country physicians, but little known beyond their immediate province, have maintained some characters. Conceiving that these must all possess some ingredients in common, he was at pains to discover it; and which he appears to have realized by obtaining among others the composition of Webb's Windsor drink. In this mixture, which is detailed below, he considers the active ingredient to be the *Plastrum* or box, which has been known as a prophylactic or balm as the doses of Hippocrates and Celsus, who both mention it. The recipe detailed below has been administered to nearly three hundred animals of different kinds, as horses, cows, sheep, swine, and dogs; and appears to have succeeded in a very great majority of the cases, where it was fully taken and kept on the stomach. It appears also to have strong prophylactic powers in the human subject; but as it would be most imprudent to trust to it alone, where caution can be practised, so it will be long before the extent of such power can be ascertained to be true. The box preventive is thus directed to be prepared:—

Take of the fresh leaves of the tree-box 2 ounces,  
of the fresh leaves of rue 3 ounces,  
of sage 4 ounces.

Chop these fine, and boil in a pint of water to half a pint; strain carefully, and press out the liquor very finely; put back the ingredients into a pint of milk, and boil again to half a pint; strain as before. Mix both liquors, which serve three doses for a human subject. Double this quantity is proper for a horse or cow. Two thirds of the quantity is sufficient for a large dog; half for a middling-sized, and one third for a small dog. Three doses are sufficient, given one on each of three subsequent mornings fasting; the quantity directed being that which forms these three doses. As it sometimes produces strong effects on dogs, it may be proper to begin with a small dose; but in the case of dogs we hold it always prudent to increase the dose till effects are evident, by the sickness, panting, and uneasiness of the dog. In the human subject, where this remedy appears equally efficacious, we have never witnessed any unpleasant or active effects; neither are such observed in cattle of any kind. About forty human beings have taken this remedy, and in every instance it has succeeded equally as with animals, but candour obliges us to notice, that in the major part of these, other means were used, as the actual or potential cautery; but in most of the animals other means were purposely omitted. That this remedy therefore, has a preventive quality is unquestionable, and now perfectly established; for there was not the smallest doubt of the animals mentioned either having been bitten, or of the dog being mad that bit them, as great pains were in every instance taken to ascertain these points.

745. To prevent similar madness Flin recommends worming of dogs, and from his time to the present it has had, most deservedly says Daniel its advocates. He tells us that he has had various opportunities of proving the usefulness of this practice, and recommends its general introduction. Blaine, on the contrary, asserts, that the practice of worming is wholly useless and founded in error; that the existence of any thing like a worm under the tongue is immediately proved to be false, and that what has been taken for it is merely a deep fissure of the skin placed there to restrain the tongue in its motions. He also observes, that the prodigious state of the tongue in what is termed dumb madness, with the existence of a partial paralysis of the under jaw by which they could not bite, having happened to dogs previously wormed, has made the inability to be attributed to this source, but which is wholly an accidental stroke. It is a very frequent disease in dogs, and is an affection of the skin, either caught by contagion or generated by the animal. The scabby mange breaks out in blotches along the back and neck, and is common to Newfoundland dogs, terriers, pointers, and spaniels, and is the most contagious. The cure should be begun by removing the first exciting cause, if removable; such as filth or poverty or as more general the contrary (for both will equally produce it), too full living, then an application should be made to the parts, consisting of sulphur and oil ammoniac ter-hme-water will also assist. When there is much heat and swelling, blood and purge. Mercurials sometimes assist, but they should be used with caution, dogs do not bear them well.

746. Worms. Dogs suffer very much from worms, which, as in most animals so in them, are of several kinds; but the effects produced are nearly similar. In dogs having the worms the coat generally stares; the appetite is ravenous, though the animal frequently does not thrive; the breath smells, and the stools are singular sometimes loose and slimy at others hard and dry, but the most evil they produce is occasional fits, or sometimes a continued state of convulsion, in which the animal lingers some time, and then dies. The fits they produce are sometimes of the violent kind; at others they exhibit a more stupid character, the dog being senseless and going round continually. The cure consists, while in this state, in active purgatives, joined with opium and the warm bath; any rough substance given internally acts as a vermifuge to prevent the recurrence.

747. The severing of whiskers is performed with a lancet, to slit the thin skin which immediately covers what is called the worm; a small wire is then to be introduced under the centre of the worm to raise it up; the farther end of the worm will, with very little force, make its appearance, and with a clock taking hold of that end, the other will be drawn out easily. The advocates for worming direct that care should be taken that the whole of the worm comes away without breaking; and it rarely breaks, unless cut into by the lancet or wounded by the awl.

748. The cat (*Felis catus L.*) is distinguished from the lion, tiger, leopard, and others of the genus *Felis*, by its annulate tail.

749. Its habits are thus given by Linnaeus:—"Inhabits woods of Europe and Asia; domesticated every where; when straying the tail, when irritated is very active; climbs, leaps, swims a field; erect when at sight, the pupil by the day a perpendicular line, by night large, round; walks with its claws drawn in; drinks sparingly; trims of the male coarctive; buries its excrements; makes a hoarse howling to its owners; moves after and plays with its kittens; wags its tail when looking after prey; the lion of mice, birds, and the smaller quadrupeds; powerful among its tribe; eats flesh and fish; refuses hot or cold things and vegetables; makes behind its ears behind a stream; makes noise in the dark; when thrown up, falls in its back; is not infested with fleas; and thirty-three days; keeps three to nine young, blind nine days; delights in martial, cat-meat, and capsaicin."

750. The cat is of great use to the farmer in catching mice, rats, and even birds. It is most desirable to keep males, as where females are kept the noisy gallantry of the adjoining tom-cats is exceedingly annoying.

7467. The Great owl (*Nyctalex flammea*) is a species of owl, with an enormous tail and spotted blackish tawny body. It is a native of Asia, Spain, and France; it hunts and easily tamed; and preserves all the properties of a cat at Constantinople and other places.

7428. The ferret (*Mustela Felo* L., fig. 922.) is an animal of the weasel and polecat kind, distinguished by its red fiery eyes.

7428. It is a native of Africa, but is tamed in Europe for the purpose of catching rabbits. It procreates twice a year, in gourd nut woods, and brings from six to eight young; small very timid. The ferret is very susceptible of cold, and must be kept in a box provided with wool or other warm materials, and may be fed with bread and milk. Its sleep is long and profound, and it awakes with a voracious appetite, which is most highly gratified by the blood of small and young animals. Its enemy to rats and rabbits is unapproachable, and when other

are, though for the first time, presented to it, it seizes and bites them with the most frenzied madness. When employed to expel the rabbit from its burrows it must be muzzled, as otherwise it will suck the blood of its victim and instantly fall into a profound sleep, from which it will awake only to the work of destruction commencing in the warren, where it was introduced only for its services, the most dreadful state and havoc. It is possessed of high irritability and when particularly excited is attended with an odour extremely offensive.

## CHAP. IX.

### Animals of the Bird kind employed in Agriculture.

7430. Though poultry form a very insignificant part of the live stock of a farm, yet they ought not to be altogether despised. In the largest farm a few domestic fowls pick up what might escape the pigs and be lost and on small farms and among cottagers, the breeding and rearing of early chickens and ducks, and in some situations the rearing of turkeys and the keeping of geese, are found profitable. There are few who do not relish a new egg or a pancake, not to say the flesh of fowls and there are some of these comforts which happily can be had in as great perfection in the cottage as in the palace. The various kinds of domestic fowls and birds which are used in agriculture may be classed as gallinaceous, or with cleft feet anserine, or web-footed, and birds of fancy or luxury. Before proceeding to the first division we shall offer some remarks on poultry hovels.

#### SECT. I. Poultry Houses and their Furniture and Utensils.

7431. The situation of the poultry house should be dry, and exposed either to the east or south-east, so as to enjoy the sun's rays in winter as soon as he appears above the horizon. Though in many cases all the commoner sorts of poultry are lodged in the same apartment yet to be able to bestow on each species its proper treatment, they ought to be separated by divisions, and enter by separate doors. Apartments for aquatic fowls may be made in part under those of the gallinaceous tribe, and the peacock often prefers roosting on a tree, or on the roof of high buildings, when it forms an excellent watch bird to the poultry-yard or farmery.

7432. Where a complete set of poultry houses are intended then a situation should be fixed on near or close to the farmery, and with ample space around for the fowls to depress over in the day-time, and one or more ponds for the aquatic sort. A space thirty feet by fifty feet may be made choice of for the building and yard (fig. 924.) the building

enclosed with a trullis or wire fence from six to eight feet in height, and subdivided with similar fences according to the number of apartments. The hen-house (a) and turkey-house (b) may have their roosts (c c) in part over the low houses for ducks (d) and geese (e), and besides these there may be other apartments (f g h) for hatching or newly hatched birds, for fattening to serve as an hospital, or for retaining, holding, or otherwise preparing food, killing poultry and other purposes. A flue may pass through the whole in moist or very severe weather the walls should be built hollow in the manner already described (PLATE.), which will at the same time be a saving of material and the windows ought to have outside shutters, both for excluding excessive heats and excessive colds. In

every apartment there ought to be a window opposite the door, in order to create a thorough draught when both are opened, and also a valve in the roof to admit the escape of the hottest and lightest air. Every door ought to have a small opening at bottom, for the admission of the fowls when the door is shut. The elevations (fig. 925.) should be in a simple style, and there may be a pagodary over the central building.

925

7426. In ordinary cases, where poultry are kept in a farm usually to produce what would otherwise be lost, either two compartments of the low wings of buildings on the south side of the yard are totally devoted to them, or any dry convenient place, according to the general plan of the farm.

7426. The position or situation of the poultry houses are very dry; the roosts are sometimes a mere floor or platform, to which the birds fly up or stand by a ladder; at other times it is nothing more than the sloping surface of the roof, or a series of cross battens; but the most approved mode is a series of rough polygonal or angular battens or poles rising in gradation from the floor to the roof, as already explained (7424. and 7425.); the battens placed at such a distance horizontally as that the birds when roosting may not intermeddle with each other by their droppings. For this purpose they should be a foot apart for hens, and eighteen inches apart for turkeys. The slope of the roof may be about 45°, and the lower part should rise up by ladders in order to admit a person to remove the dung. No flying is requisite in the case of such a roost, as the birds ascend and descend by steps.

7428. Nests are sometimes fixtures, in which case they are niches built against the wall, not unlike wine bins; where there is more than one tier on the ground floor each superimposed tier must have a projecting balcony in front of about a foot in width, with stairs of ascent at convenient distances.

7428. A nest better for preserving food may sometimes be requisite, though on a small scale this may be done in the kitchen. Winter troughs are generally fixed in the yard. In confined situations there should be a large colony of sand, in which the fowls may nestle and roll about in order to free themselves from vermin. There should also be a spot composed of gravel, sand, and soft earth, for nearly the same purpose, but more especially for exercising the young chickens. A roof for shelter and protection from the sun may very appropriately be placed over this last compartment, or a part of it.

7427. The utensils are the portable nest, (fig. 926 a), coops (b c) portable shelter (d) feeding dishes

926

corn has for retaining a store of food, egg basket, and feather bag. We avoid enumerating the utensils used in coining, considering that unwholesome and disgusting practice as unfit for the present age.

An improved poultry feeder (fig. 927) has lately been published in the *Transactions of the Highland Society*. It is made to hold half a quarter of grain, not one particle of which can be lost. When once filled, it requires no more trouble, as the grain falls down into the receiver below as the fowls pick it away; and the covers on that, which are opened by perches, and the iron cover above, which is secured by a padlock, completely keep the grain from the rain, so that the fowls get it always quite dry, and as nothing less than the weight of a hen on a perch can lift a cover on the lower receiver, sparrows, and other small birds are completely excluded, whilst the small cross bars through which the fowls pick prevent cattle and other large animals from getting at the grain. It is astonishing with what facility the fowls learn to leap upon the perch, and so open the cover of the receiver which covers the grain.

927

## SECT. II. Gallinaceous Fowls, their Kinds, Breeding, Rearing and Management.

7428. Under the order Gallinae are included the common hen, turkey, Guinea, and peacock; and we shall here treat of each of these birds in succession.

7428. The different species of fowls, that is, of cocks and hens, inhabit in their native state the continent

928

and islands of Asia and India. Naturalists have not agreed whether these numerous varieties of this most useful bird, even in a domesticated state, have originated from one or from two species. M. Temminck considers the Bankiva cock (*Gallus Bankiva*) as the origin of our domestic poultry; while others think they may have sprung from the Jungle cock (fig. 928. G. *Bankiva*), still found in the greatest plenty in the forests of India. The term chicken is applied to the female young of gallinaceous animals till they are four months old; afterwards they are called pullets, till they begin to lay when they become hens. The male is a cock till he is three months old, then he is a cock bird till the age of twelve months, when he becomes a rook; unless, indeed, he has been artificially deprived of the faculty of procreation, when he becomes a capon; and when the ovaries are taken from a pullet or hen, she is called a hen capon.

7440. The duration of a bird so long under culture may naturally be expected to be numerous, those most esteemed in Britain, at the present time, are the following:—

7440. The common domestic cock and hen, besides these, of every colour, and variety.

7441. The peacock and hen (fig. 929). The peacock is said, but only in fact, to be generally red or brown, black white, and so

superior to that of any other variety for stickness and delivery of flavour; eggs small, fine shaped, and

short, five claws on each foot eggs large, and lays abundantly

colour of the flesh inclining to yellowish or ivory. Both hens and cocks often made into capons.

7443. The *Darling* cock and hen (fig. 930) so called from the town in Surrey of that name, is the largest variety; shape handsome body

subvariety of the above, of Dutch origin they are of smaller size, and said to be ever-laying layers. Their

7444. The *Feland* cock and hen (fig. 931) were originally imported from Holland. The colour shining black, with white legs on the head of both cock and hen head flat, surmounted by a fleshy protuberance out of which spring the crown feathers, or top, white or black, with the fleshy king David's crowns (the *oriental* in heraldry) consisting of four or five spikes; their turn plump and deep; legs short, but with five claws lay abundantly are less inclined to set than any other breed; they fatten quickly, and are more juicy and rich than the Dorking. On the whole, this is one of the most useful varieties. There is an ornamental subvariety known as the golden Feland (h) with yellow and black plumage.

known as well as good layers. There are two varieties of this breed, remarkable for having the

7445. The *London* cock and hen (fig. 932) is a small Indian breed, valued chiefly for its grotesque figure and delicate flesh. Mowbray mentions a subvariety, extremely small, and as smooth-legged as a game fowl. From their size and delicacy they are very convenient, as they may always be used as substitutes for chickens, when small ones are not otherwise to be had. They are also particularly useful for sitting upon the eggs of partridges and pheasants, being good

7446. The *Chittagong* or *Moulay* hen (fig. 933) is an Indian breed, and the largest variety of the species. They are in colour striped, yellow and dark brown; long necked, upright-headed, and high upon the leg; their flesh dark, coarse, and chiefly adapted to soup. They are good layers; and being well fed produce large, substantial, and nutritious eggs; but these birds are too long-legged to be steady sitters.

7447. The *Muscovy* or *Duck* of *Leeds* breed, was formerly in great repute, but is now nearly lost. It is sometimes to be met with at Wokingham (Oxfordshire), in Berkshire, and is as large, and the flesh as white, firm, and fine, as to afford a convenient substitute for the turkey.

7448. The *Downy* *Spanish* cock and hen is a cross between the Dorking and Spanish breed, also to be found in and around Wokingham. It is a large bird with black plumage, white and delicate flesh, the largest eggs of any British variety and well adapted for capons.

7451. The health of *hens* is observable in the front and breast colour, or the colour, and the healthy gloss of the plumage. The most useful cock is generally a bold, active, and savage bird, sometimes cruel and destructive in his fits of passion, if not well watched, to his hens, and even to his neighbours. Hence above the common size of their respective varieties are by no means preferable either as layers or sitters. The indications of old age are paleness of the comb and gills, dulness of colour, and a sort of downy stiffness in the feathers, and length and slenderness of the scales upon the legs becoming large and prominent.

7452. The number of *hens* to one cock should be from four to six, the latter being the extreme number with a view of making the utmost advantage. Ten and even twelve hens have been formerly allowed to one cock, but the produce of eggs and chickens under such an arrangement will seldom equal that to be obtained from the smaller number of hens. Every one is aware that the spring is the best season for commencing breeding with poultry, and in truth it scarcely matters how early, presupposing the best food, accommodation, and attendance, under which hens may be suffered to sit in January.

7453. The conduct of the cock towards his hens is generally of the kindest description, and sometimes, as in the Polish breed, so remarkably so, as to be quite incredible to those who have not witnessed it. It is not an uncommon occurrence, however, for the cock to take an antipathy to some individual hen; when it continues for any length of time it is best to remove her and supply her place by another, taking care that the stranger be not worried by the hens. Spare coops or houses will be found useful on such occasions.

7454. The change of a cock, from death or accident, is always attended with interruption and delay, as it may be some considerable time before the hens will associate kindly with their new partner; and further, a new cock may prove dull and inactive from the change, however good in nature. This frequently happens with cocks of the superior breeds, purchased from the London dealers, in whose coops they have been kept in such a high state of temperature, that they are unable to endure the open air or the country unless in the summer season. Such being removed in autumn, winter or early in spring, if immediately turned abroad with hens, are liable to become aguish, torpid, and totally useless; perhaps, in the end, turning rousy or pandered. The only method of safety in this case is to keep such a cock in the house, upon the best and most nourishing food, turning him several times in the day and permitting him to be abroad an hour or so, the weather being fine, until, in a few weeks, he shall be accustomed to the air.

7455. In making the nest short and soft straw is to be preferred; because, the straw being long, the hen on leaving her nest, will be liable to draw it out with her claws, and with it the eggs. The hen, it is ascertained, will brood and lay eggs without the company of a cock, of course, such eggs are barren.

7456. Eggs for setting should never exceed the age of six weeks, as nearly as possible, and of the full middle size void of the circular flaw which indicates the double yolk, generally unproductive, nor should there be any roughness or cracks in the shells. The number of eggs, according to the size of the hen, from nine to fifteen, an odd number being preferable, on the supposition of their laying more eggs. The eggs to be marked with a pen and ink, and examined when the hen leaves her nest, in order to detect any fresh ones which she may have laid, and which should be immediately taken from her, as they if not laid, would be hatched too late for the brood. It is taken for granted the hen and nest have been made perfectly clean for the reception of the hen and that a new nest has not been slightly or hastily thrown upon an old one, from the filth of which vermin are propagated to the great annoyance of the hen, and prevention of her steady sitting. Eggs broken in the nest should be cleared away the instant of discovery and the remaining washed with warm water and quickly replaced, but these adhere to the hen, and be drawn out of the nest. If necessary, the hen's feathers may also be washed, but always with warm water.

7457. With respect to the superintendence of some hens in the article of sitting, it is a risk which must be left to the judgment of the attendant, who has to determine whether the hen which appears desirous of sitting may be safely trusted with eggs. Leaving a number of eggs in the nest is an enticement. Very frequently a hen will sneak, and appear hot for incubation, yet after sitting over her eggs a sufficient number of hours to addle them, will then desert them and, probably in the course of a few days will be taken with another fit of incubation. Much useless cruelty is too often exercised to prevent the hen from sitting, when eggs, rather than chickens, are in request. A late author recommends to thrust a straw through the hen's nostrils, in order to prevent her from sitting; and to give her half a glass of gin, then swing her round until seemingly dead, and confine her in a pot during a day or two, leaving her only a small smelling herb, to force her to sit! It is full time that those and a hundred other such utterly useless and barbarous follies of former days grounded upon various animals should be dismissed with the contempt they merit. The pamphlet alluded to in the *Epitome*, by Thomas Young, a publication replete with good things on the interesting subjects of sitting, wine, spirits, beer, cider &c. It is written with *humour*. (Mistake)

7458. Moulting. Every succeeding year after the third, the hen continues to moult later in the season, and laying fewer or no eggs during the moulting period, which is sometimes protracted to two or three months. It should be noted that old hens are seldom to be depended upon for eggs in the winter, each being scarcely full of feather until Christmas; and then, probably may not begin to lay till April, producing at least not more than twenty or thirty eggs. In general, it is most profitable to dispose of hens whilst they are yet capable or capable for that purpose, which is in the spring of the third year. Nor do delicate white hens lay so many eggs in the cold season as the more hardy coloured varieties, requiring warmth and shelter, particularly by night. Moulting, or the moulting and renewal of feathers, last which its effects from one to three months, according to the breed and strength of the bird. Whilst under this natural course, poultry are unfit for the table, as well as for breeding. It is the same with respect to young poultry whilst shedding their feathers in the spring. The regular moulting of full-grown birds begins in the autumn.

7459. As *hens* have the desire of association is so powerful that they will repeat it five or six times in the year; so often it is so slight, that they will probably sit at more than once or twice in the season. A skilled feeder will take advantage of this, and provide abundance of eggs from the one variety, and of chickens by means of the other. Hence, when sitting, drink more than usual and it is an advisable practice to place water constantly before them when in this state, and feed (say once) at least twice a day. The time of incubation is twenty-one days.

7460. Hatching. The chicken, hatched up like a ball, with its bill under the right wing, like a bird when, begins generally on the morning of the twenty-second day to break its way through the shell; within the hen, may see the art of man, with every member there, and in this very interesting and prodigious operation. The greatest affection of the hen, as Monstrey and Pharrastier have observed, is almost

intensely interested, when she did learn the value of the advice. Through the shells, and the strokes of their bills into against them. The eggs of a nest of chickens, the farmer would observe, are the egg being partly packed, and the object of the packing is to prevent the eggs from being broken. The shell may then be broken, and the body of the chicken, which is separated from the eggs, will then be broken. The farmer says it is his opinion, that no aid ought to be given to any chickens but those which have been kept twenty-four hours employed without getting forward in their work.

7481. The chicken's first assistant should be taken from the hen, but she be tempted to leave her that intention. These removed may be secured in a basket of wood or soft hay, and kept in a moderate heat, if the weather be cold, near the fire. They will require no food for many weeks, even four-and-twenty should it be necessary to keep them so long from the hen. The whole brood being hatched, the hen is to be placed under a coop closed, upon a dry spot, and, if possible, not within reach of another hen, since the chickens will mix, and the hen is apt to suffer or destroy those which do not belong to them. Her should they be placed next numbers of young fowls, which are likely to crush young chicks under their feet, being always eager for the chickens' meat. The first food should be split grain, afterwards tall wheat; all victory food, soaked bread, or potatoes, is improper. Eggs boiled hard, or cold chopped meat, are much approved as first food. Their water should be pure and often renewed; and there are convenient pans made, in such forms that the chickens may drink without getting into the water, which often, by wetting their feet and feathers, muddies and injures them. A basin wheeled in the middle of a pen of water will answer the end, the water running round it generally and, independently of situation, and the disposition of the hen, there is no necessity for cooping the brood beyond two or three days but they may be confined as occasion requires or suffered to range, as they are much benefited by the scratching and foraging of the hen. They must not be let out too early in the morning, or while the dew remains upon the ground, for less be suffered to range over the wet grass, one common and fatal cause of disease. Another caution is of the utmost consequence, to guard them watchfully against sudden unfavourable changes of the weather, more particularly if attended with rain. Nearly all the disorders of gallinaceous fowls arise from cold moisture.

7482. For the period of the chicken's getting the hen, there is no general rule the most certain is, when the hen begins to rook, leaving them, if sufficiently forward, they will follow her; if otherwise, they should be secured in a proper place, the time having arrived when they are to associate with the young poultry as nearly of their own age and size as possible, since the larger are apt to overrun and drive from their rook the younger brood.

7483. Hatching by artificial heat is an Egyptian practice, mentioned by Diodorus and Aristotle, and was brought into notice about the middle of the sixteenth century by Basconar in his *Art de faire d'oeufs, de des Chœnes domestiques*. The requisite degree of heat is 90 degrees, which is supplied by fire, steam, hot water or fermentable substances. After hatching the birds are placed in a cage, in which is placed a lamb-skin suspended from the roof of a box, and enclosed by a curtain of green baize or according to Parmentier they may be placed under a capon, which after being prepared for receiving pleasure from feeling the chickens under its belly by depriving it of the greater part of the feathers and excoriation, is to be confined with them in the same coop, and after being fed together for a day or two it is said the capon will become an excellent nursing mother. Excepting as matter of curiosity however it is not at present worth while either to hatch or rear chickens artificially in this country. Whether Bauman's mode of hatching be adopted, or Mrs D'Oyley's of depriving hens of their chickens as soon as hatched and thus causing one hen to hatch five or six broods in succession the human attention required, and the risk of failure are so great, that the surest modes, under all the present circumstances, are such as are natural. Where it is tried for experiment or curiosity the heat of ten or eleven is more likely to prove steady than that from smoke, air or steam, probably even than that of hot water successfully tried, however, and, we believe, still practised in the neighbourhood of Paris. An enclosure in the middle of a broad vinery or dovecote might serve at once to hatch and rear early chickens and such a mode of rearing, at least in the winter season, certainly deserves the attention of those who are curious in having this luxury in February and March. In 1822 or 1823 some interesting experiments were exhibited by Mr Barlow at the Egyptian Hall, London, relative to an improved method which he had invented, of hatching eggs by artificial heat. The method, and the machine necessary to practise it, seem to have come very little into use.

7484. The incubation of chickens by hot water is the invention of M. Bonnemant, physician, of Paris, in 1777 and still alive when we were in that capital in 1822. Chickens hatched in this way at St Germain, under M. B's direction, it is said, supplied the table of Louis XIV. The boiler of the apparatus is called a *calorifère*, (calor, heat, and ferre, to bear,) and consists of a small boiler (Fig 356. c) a box or

934

building (b) for hatching the eggs, a cage or coop (c) for rearing the chickens, tubes (d) for circulating the hot water, a supply tube and funnel (e), and a safety tube (f). Descending the water level in the boiler, it will rise by its specific levity through the tube (a, d), move progressively through all the tubes, and return again to the boiler by the tube (g) which is inserted in the lid like the other but opens down to its lower part (h). This circulatory movement, once commenced, continues so long as the water is heated in the boiler, because the temperature is never equal throughout all parts of the apparatus. We may readily conceive that a perfect equality of temperature can never exist, an amount of the constant heat of heat, which escapes from the extremities of all the tubes. Meanwhile, the temperature of the air in

closed in the last, differs but little from that of the numerous tubes which traverse it; and in the centre of the latter, or the centre of the last, after but little notice to be paid, by the thermometer, to the heat of the atmosphere, which is always in the ratio of the difference between the temperature of the water passing out of the cylinder and returning it, does not become greatly diminished, even after having expended a large portion of its heat on the outside of the box, in maintaining a gentle heat in the eggs (c) adjoining it. We see, therefore, that the more the water is cooled whilst it passes through the last circumference of the tubes, the more active is the circulation in all parts; and, consequently, the more rapid is the temperature of all the tubes which heat the last, and of the air which it is desired to prevent the loss of heat as much as possible, the better, and all these parts of the tubes which are placed on the exterior of the box, are enveloped in lots of woollen cloth. Mr. Beaumont having thus applied these principles with as much skill, is always enabled to maintain in these boxes an equal temperature, varying scarcely so much as half a degree of Fahrenheit's thermometer; but, as if it was not sufficient to have done for himself the problem, he conceived that this degree of temperature in all parts of the stove should be maintained at that point which was found most favorable for promoting incubation. It was by means of an apparatus for regulating the fire that he obtained this desirable object. The action of this regulator is founded on the unequal dilation of different metals by heat. A movement is communicated near to the axle of a balanced lever, which lever transmits it by an iron wire to a register in the main-gate door of the furnace. Combustion is by these means abated or increased. The details of this piece of machinery are fully described and delineated in *Gard's Technological Repository* (Feb. 1836, p. 70).

7468. *When we would hatch chickens by hot water* we light the fire and raise the temperature till we obtain that degree of heat in the box which is fitted for incubation; we then place the eggs near to each other upon the shelves, with borders in them (f), which are fixed under each row of tubes. It is not necessary not to cover, on the first day, more than a fourth part of the superficiality of the shelves, and to add every day, for twenty days, an equal quantity of eggs, so that, on the twenty first day, the quantity of eggs first placed will be, for the greatest part, hatched, so that we may obtain every day nearly the same number of chickens, but which may nevertheless, be occasionally regulated by the particular season of the year.

7469. *During the first days of incubation*, whether natural or artificial, the small portion of water contained within the substance of the egg evaporates through the pores in its shell; this is replaced by a small quantity of air, which is necessary to support the respiration of the chick; but as the atmosphere air which surrounds the eggs in the box at that degree of temperature is either completely dry or but little humid, so the chicks would greatly suffer or finally perish, from this kind of desiccation. The aqueous vapour which exhalates from the breathing of the old fowls while hatching, in some degree prevents this ill effect; but, nevertheless, in dry seasons, the vapour is hardly sufficient. And thus, in order that the eggs may be better hatched in the dry season, the house covers them with the earth of the floor of the granary in artificial incubation, to keep the air in the stove constantly humid, they place in it flat vessels, such as plates (h, k), filled with water. When the chickens are hatched they are removed from the stove, and carried to the cage (e), where they are fed with millet, and peck under a sheep's skin with wool on it (f), suspended over them. They also separate, by means of partitions in the cage, the chickens as they are hatched each day, in order to modify their nourishment agreeably to their age. Artificial incubation is exceedingly useful in hatching young fowls at those seasons when the hens will not sit, and, in some situations, to produce, or, as we may say indeed, to manufacture a great number of fowls in a small space. (*Gard's Technological Repository* No. vii. p. 73, as quoted in *Gard. Mag.* vol. iv. p. 307.)

7467. *The products of the cock and hen* are eggs, feathers, and the carcass.

7468. Eggs become desiccated, and, in consequence, lose great part of their substance and nutritive quality, by keeping; and every body knows the value of a fresh-laid egg. They will retain their moisture and produce, however, three or four months, or more, if the pores of the shell be closed and rendered impervious to the air by someunctuous application. We generally anoint them with mutton suet melted, and set them on end, wedged close together, in bran, *stratum super stratum* the containing box being closely covered. Laid upon the side, the yolk will adhere to the shell. They thus come into use, at the end of a considerable period of time, in a state almost equal to new laid eggs, for consumption; but ought not to be trusted for incubation, excepting in the case of the vapoured eggs of rare birds.

7469. *The largest eggs* will weigh two ounces and a half, those of the Chittagong hen perhaps three ounces. To promote fecundity and great laying in the hen, nothing more is necessary than the best corn and fair water; baked or sprouted barley has occasionally a good effect, whilst the hens are kept on solid corn, but if continued too long they are apt to sour. Cordial horse-bell is good to promote laying in the cold season, and also tansy and ale, as every housewife well knows. It must be noted, that nothing is more necessary towards success in the particular of obtaining plenty of eggs, than a good attendance of cocks, especially in the cold season, and it is also especially to be observed, that a cock whilst moulting is generally useless. Buffon says, a hen well fed and attended will produce upwards of one hundred and fifty eggs in a year besides two broods of chickens. Mowbray observed, that a hen generally cackled three or four days previously to laying; and that some half-fred game hens began to lay as soon as their chickens were three weeks old; the consequence of high keep and good attendance of the cocks.

7470. *Feathers or down* intended for use should be plucked as soon as possible after the bird is dead, and before it is cold, otherwise they are defective in that elasticity which is their most valuable property, and are liable to decay. The bird should, besides, be in good health, and not moulting, for the feathers to be in perfection and being plucked, and a sufficient number collected, the sooner they are dried upon the oven the better, since they are also apt to heat and stick together.

7471. *The feathers of birds* are applied to various purposes of utility and ornament. "The plumnifer cuts and prepares the delicate feathers of birds, and gives them the most brilliant colour, in order to vend them to the embroiderer, and the manufacturer of artificial flowers, who introduces them into their embroidery, and inserts them into bouquets and garlands, to add to the elegance of dress and furniture, according to the tastes indicated by fashion. The plumnifer only employs the feathers of the stork, the heron, the peacock, the swan, the goose, and the cock; these he prepares and disposes in a fit manner to adorn our hats, robes, &c.; he also makes eyebrows and an infinity of other objects. The workman who forms the feathers for these uses is termed a plumnifer. All the kinds of feathers which possess great brilliancy of tint, and fineness, are also employed in a great variety of circumstances, although these are preferred which we have above mentioned." (*Gard's Tech. Rep.* vol. vi. See p. 568.)

7472. *Where hens are kept more than a year* they are sometimes plucked towards the end of the spring season for the sake of their feathers. This operation, where it takes place, ought to be performed in the most tender and careful manner, and the birds housed afterwards for a time sufficient to enable them to acquire the air; but the practice is cruel, and we trust it is not likely to come into general use.

7473. *Feeding and fattening the persons.* Fowls will become fat on the common run of the farm-yard, wherever there are upon the table of the stable, and other refuse, with perhaps some small regular daily feed; but at those times they become particularly fat, and are thus styled barn-door fowls, probably the most delicious and high flavored of all others, both from their full allowance of the finest corn, and the constant haste to which they are kept, by living in a natural state, and having the full enjoyment of air and exercise. They are also employed in a certain number of weeks, in cooking, those fowls which are spent ready being always in vogue. It is a common practice with some housewives, to keep their barn-door fowls for a week or two, under the notion of improving them for the table, and increasing their fat, a practice which, however, seldom succeeds, since the fowls generally pine for their loss of liberty

and fighting their food, less instead of gaining additional flesh. Such a period, in fact, is too short for them to become accustomed to confinement.

7474. *Feeding fowls should be warm and dry, with earth floors well raised, and impervious enough to accommodate thirty fowls. The floor slightly tilted down, and the litter often changed. Sandy gravel and a little straw which should be placed in different places, and often changed. A sufficient number of troughs, for both water and food, should be placed around, that the stock may feed with as little interruption as possible from each other, and perches in the same proportion should be furnished for those fowls which are inclined to perch, which few of them will desire after they have begun to fatten, but which helps to keep them easy and contented until that period. In this mode fowls may be fattened to the highest pitch, and yet preserved in a healthy state, their flesh being equal in quality to that of the barn-door fowl. To suffer fattening fowls to perch is contrary to the general practice, since it is supposed to bend and deform the breast-bone; but as soon as they become heavy and indolent from feeding they will rather incline to rest in the straw and the liberty of perching in the commencement of their cooping has a tendency to accelerate that period, when they are more inclined to rest on the floor. Fowls, moreover, of considerable growth will have many of them become already smothered beneath a corn-patch ing whilst at large, although much depends upon form in this case, since well aged cocks and hens of the best shape which have perched all their lives with the breast bone perfectly straight.*

7475. *The provision of light, by inclining fowls to a constant state of repose excepting when moved by the appetite for food, promotes and accelerates obesity, but a state of obesity obtained in this way cannot be a state of health, nor can the flesh of animals so fed equal in flavour, nutriment, and salubrity that of the same species fed in a more natural way. Economy and market interest may perhaps be best answered by the plan of darkness and close confinement, but a feeder for his own table, of delicate taste, and anxious of furnishing his board with the choicest and most nutritious viands, will declare for the natural mode of feeding; and in that view, a feeding yard, gravelled and turfed, the room being open all day, for the fowls to retire at pleasure, will have a decided preference, as the nearest approach to the barn-door system.*

7476. *Insects and animal food form a part of the natural diet of poultry are medicinal to them in a weakly state, and the want of such food may sometimes impede their thriving.*

7477. *For fattening the younger chickens the above feeding room and yard is well calculated. These may be put up as soon as the hen shall have quitted her charge, and before they have run off the sucking flesh, for generally, when well kept and in health they will be in fine condition and full of flesh at that period, which flesh is afterwards expended in the exercise of foraging for food, and in the increase of stature, and it may be a work of some time afterwards to recover it, more especially in young cocks, and all those which stand high upon the leg. In fact, all those which appear to have long legs should be fattened from the hen, to make the best of them. It being extremely difficult, and often impossible, to fatten long-legged fowls in coops, which, however, are brought to a good weight at the barn-door.*

7478. *In the choice of fattening fowls for feeding, the short-legged and earl's, hatched always deserve a preference. The green helmet is an excellent model of form for the domestic fowl, and the true Dorking breed approaches the nearest to such model. Of course the smaller breeds and the game are the most delicate and soonest ripe. The London chicken butchers as they are termed, or poulterers, are said to be of all others the most dexterous feeders, putting up a coop of fowls and making them thoroughly fat within the space of a fortnight, using so much grease, and that perhaps not of the most delicate kind, in the food. In the common way this business is often badly managed, fowls being huddled together in a small coop, tearing each other to pieces, instead of enjoying that repose which alone can ensure the wanted for object. Irregularly fed and cleaned until they are so stretched and pinched in their own excrement, that their flesh actually smells and tastes of it when smoking upon the table. Where a steady and regular profit is required from poultry the best method, whether for domestic use or sale, is constant high keep from the beginning, whence they will not only be always ready for the table with very little extra attention, but their flesh will be superior in juiciness and rich flavour to those which are fattened from a low or emaciated state. Fed in this mode, the spring pullets are particularly fine, and at the same time most nourishing and restorative food. The pullets which have been hatched in March if high fed from the nest, will lay plentifully through the following autumn and not being intended for breeding stock, the advantage of their eggs may be taken, and themselves as disposed of thoroughly fat for the table in February, about which period their laying will be finished. Instead of giving ordinary and tail corn to fattening and breeding poultry it will be found most advantageous to allow the heaviest and best, putting the confined fowls upon a level with those fed at the barn-door, where they have their share of the weightiest and finest corn. This high feeding shows itself not only in the size and flesh of the fowls, but in the size, weight, and substantial goodness of their eggs, which in those valuable particulars will prove far superior to the eggs of fowls fed upon ordinary corn or weedy potatoes, two eggs of the former going further in domestic use than three of the latter. The water also given to fattening fowls should be often renewed, fresh and clean. Indeed, those which have been well kept will turn with disgust from ordinary food and foul water.*

7479. *Barley and wheat are the great dependence for chicken poultry, oats will do for full-grown hens and cocks, but are not so good as barley both when they have their fill of corn, will eat occasionally eat bags or best leaves. Steamed potatoes and oatmeal mixed together make an excellent mess, but must not be given in great quantities, otherwise it renders the flesh soft and fatty.*

7480. *Cramming. Barley and wheat are generally the basis or chief ingredient in all fattening mixtures for chickens and fowls, but in Sussex ground oats are used and there oats are in higher repute for fattening than elsewhere, many large hogs being fattened with them. In the report of that county the Rev. Arthur Young says, "North Chappel and Kimford are famous for their poultry, they are fattened there to a size and perfection unknown elsewhere. The food given them a ground oats made into gruel, mixed with bog's grease, sugar, pot-liquor and milk, or ground oats, treacle, and meat, sheep's pluck, &c. The fowls are kept very warm, and crammed morning and night. The pot-liquor is mixed with a few handfuls of oatmeal and boiled, with which the meal is kneaded into crams or rolls of a proper size. The fowls are put into the coop two or three days before they are crammed, which is continued for a fortnight, and they are then sold to the highest. These fowls, full grown, weigh seven pounds each, the average weight five pounds, but there are instances of individuals double the weight. They were sold at the time of the survey (1809) at four to five shillings each. Turner of North Chappel, a tenant of Lord Egremont, crams two hundred fowls per annum. Great art and attention is requisite to cut the capons, and numbers are destroyed in the operation.*

7481. *Oatmeal is in Derby a particularly famous fattening food, by which many persons in that town and country gain a livelihood. The fowls are sold to the London dealers, and the sum of 180*l.* has been returned in one market-day by this traffic. Twenty dozen of these fowls were purchased for one guinea at Wundser after the rate of half a guinea the couple. At some seasons, fifteen shillings have been paid for a couple. Fowls constitute the principal commerce of the town. Romford, in Essex, is also a great market for poultry but generally of the store or barn-door kind and not artificially fed.*

7482. *The Oakingham method of feeding is to confine the fowls in a dark place, and cram them with paste made of barley meal, molasses, treacle, or brown sugar and milk, and they are fatted completely ripe in a fortnight. It keeps longer the fatter that is induced by this continued state of repletion, renders them red and unsaleable, and frequently kills them. Geese are likewise fed in the same neighbourhood, in great numbers, and sold about midsummer to itinerant dealers the price at the time the survey was made (1809), two shillings to two and three-pence each. It appears utterly contrary to reason, that fowls fed upon such greasy and impure mixtures can possibly produce flesh or fat so fine, delicate, high flavoured,*

or moulting, or those fattened upon more simple and substantial food; as, for example, meat and milk, without the addition of either treacle or sugar. With respect to grease of any kind, its chief effect must be to render the flesh luscious and of indelible flavour. Nor is any advantage gained, extending the commercial use.

7483. The methods of crowning by confining in a box the size of the body of the fowl, and allowing its head and vent to project for intrusion and ejection; of blinding the bird for this purpose; or of nailing it to the board; and also the mode of forcing down liquid food by a particular kind of pump, worked by the foot of the feeder; all these and other cruel practices we wish we could abolish in practice, and send to the flames from the printed page.

7484. *Caponisation* is performed on cocks and hens only in some districts, and chiefly in Berkshire and Sussex. The usual time is when they have left the hen, or when the cocks begin to crow, but the earlier the better. It is a barbarous practice and better omitted. Capons are shunned both by hens and cocks, which, it is said, will not roost on the same perch with them. The Chinese mode of making capons is fully described and illustrated with cuts in the *Farmer's Magazine*, vol. vi. p. 46.

7485. *Feathering of fowls* is often practiced to restrain them from roosting too high or from flying over fences, &c., and is much more convenient than the cutting their wing feathers only. But in the ordinary methods of merely excising the pinion, it is frequently fatal; and almost always so to full-grown birds or fowls, by their bleeding to death. To prevent this in the long-winged tribes, as ducks, geese, &c. pass a threaded needle through their wing, close by the inside of the smaller bone (fig. 935 a) and making a ligature with the thread across the larger bone, and returning it on the outside of all, the principal blood-vessels are secured, which could not be accomplished by a ligature confined to the surface only. After the blood-vessels have been thus secured cut off the portion of wing beyond the ligature with scissors or shears. In the Gallinæ or short-winged tribes, as cocks, hens, &c. the operation is rendered easier by being performed on the beginning of the next joint (b),

making the ligature embrace all the vessels between these two bones by passing it twice through and securing each bone individually and passing the ligature around the whole of that part of the wing generally. In this way also birds which have been accidentally winged in shooting may be preserved.

7486. The turkey (*Melagris Gallinæ L.*, fig. 936) is a native of America, and was introduced into this country from Spain soon after the discovery of the former country. The colour in the wild state is black, but domestication has produced great variety.

7487. In a state of nature they are said to parade in flocks of five hundred, feeding, in general, where abundance of berries are to be found, the seed of which and of a small red acorn is their common food in the American woods. They get fat in a wild state, and are soon run down by hawks and dogs. They roost on the highest trees, and since the clearing of extensive tracts in America, have become rare in many places. Their antipathy to any thing of a red colour is well known. In this country they are supposed to be of a tender constitution, which only applies to them when young: for when grown up they will live in the woods with occasional supplies of food, as is actually the case to a great extent in the desolate lands of the *Manana* of Sicily, in Sicily.

7488. The varieties are few and chiefly the copper and white, said to be imported from Holland, the former too tender for general culture; the black Norfolk is esteemed superior to all others.

7489. *Breeding.* One turkey cock is sufficient for six hens or more, and a hen will cover according to her size from nine to fifteen eggs. The hen is apt to turn her nest abroad in a hedge, or under a bush, or in some secure place. She lays from eighteen to twenty-five eggs or upwards, and her term of incubation is thirty days. She is a steady sitter even to starvation and therefore requires to be regularly supplied with food and water. Buffon says she is a most affectionate mother, but Mowbray observes, that from her natural headlessness and stupidity she is the most careless of mothers; and being a great traveller herself, will drag her brood over field, heath, or bog, never casting a regard behind her to call in her straggling chicks, nor stopping while she has one left to follow her. The turkey differs from the common hen in never scratching for her chicks, leaving them entirely to their own instinct and industry: neither will they fight for their brood, though vigilant in the discovery of birds or prey when they will call their children together by a particular cry, and run with considerable speed. Hence when not confined within certain limits, they require the attendance of a keeper.

7490. Turkey chicks should be withdrawn from the nest as soon as hatched, and kept very warm by wrapping them in flannel, or putting them under an artificial mother in a warm room or other warm place. Various nestures are recommended to be given and done at this season, as a pepper-water and a tea-spoonful of milk, immersion in cold water, &c. Mowbray wisely rejected all these unnatural practices, and succeeded by giving curd and hard eggs, or curd and barley meal kneaded with milk, and renewed with clear water rather than milk, as he found the last often scoured them. A sort of vermicelli, or artificial worms, made from pulling boiled meat into strings, he found beneficial for every species of gallinaceous chickens. Two great objects are, to avoid superfluous moisture, and to maintain the utmost cleanliness, for which purpose as little shop food is given as possible. A fresh turf of short sweet grass should be daily given as green food, but not made or wormed or scoured, and no cats; needle seed, clover, rye, or unsown seed gathered, as recommended by the elder housewife. Water is generally preferable to milk. When the weather is favourable, the hen is couped abroad in the forenoon. During the rest of the day and night, for the first six weeks, she is kept within doors. After this the hen may be couped a whole day alternately for another fortnight, to harden the chickens; and afterwards they may be left to range within certain limits, or tended by an old man or woman, being fed at going out in the morning and returning in the evening. Their ordinary food may be that of the common fowls and hens. They will prefer roosting abroad upon high trees in the summer season, but that cannot generally be permitted with a view to their safe keeping.

7491. *Feeding.* Sudden barley or barley and wheat-meal mixed, is the most approved food, and the general mode of management is the same as that of the common cock and hen. They are generally fed as we do come in at Christmas, but they may be fattened early or late. Sometimes though, but rarely, they are caponed. Such as the wild turkey of America has been known to attain the weight of sixteen pounds; the Norfolk turkeys are said sometimes to weigh twenty and thirty pounds; but Mowbray says,

he never made any higher than fifteen pounds ready for the spit. The living and dead weight of a turkey are as 21 to 15.

7493. *Poultry*. Turkeys are sometimes plucked alive, a barbarous practice which ought to be laid aside. Farmers proposed to multiply the breed of white turkeys in France, and to employ the feathers found on the lateral part of the thighs instead of the plumes of the ostrich.

7495. *The Guinea hen* (*Numida meleagris* L., fig 937) is found in a wild state only in Africa, from whence it has been diffused over every part of Europe, the West Indies, and America. In a state of nature these birds associate in flocks of two or three hundred. They delight in marshy places, but always perch during the night in trees, or high situations. It is bigger than a large cock, and is active, restless, and courageous and will even attack the turkey, though so much above its size.

7494. *The properties of the pheasant and the turkey have been said to be united in this bird*—its flesh is more like that of the pheasant than that of the common cock and hen both in colour and taste, and is reckoned a very good substitute perfectly with common fowls in its artificial habits and kinds of food; but it has this peculiarity—that the cocks and hens are so nearly alike, that it is difficult to distinguish them, and it has a peculiar gait, and cry and chuckle.

7495. *The peacock* (*Pavo cristatus* L.) is a native of India, and found in a wild state in Java and Ceylon, where they perch on trees like the turkey in America. The age of the peacock extends to twenty years, and at three the tail of the cock is full and complete. The cock requires from three to four hens and where the country agrees with them, they are very prolific, a great ornament to the poultry yard and lawns, and useful for the destruction of all kinds of reptiles. Unfortunately they are not easily kept within moderate bounds, and are very destructive in gardens.

They live on the same food as other domestic fowls, and prefer barley. They are in season from February till June but though a peacock forms a very showy dish, the flesh is ill-coloured and coarse, and they are therefore kept more as birds of ornament than of use.

7496. *The crested curassow* (*Crax Albotus* L., fig 938.) is a beautiful and majestic bird, nearly the size of a turkey—it is common in some parts of tropical America, and is mentioned as being abundant in Paraguay. In those countries it is tamed, and readily associates with the other domestic poultry. Like most gallinaceous birds, it lives in flocks of about a dozen, feeds upon Indian corn, rice, and other grain during the day and roosts on high trees at night.

Its size, disposition, and the delicacy of its flesh, all recommend our attempting to domesticate it in this country.

### SECT. III. *Anserine or Aquatic Fowls.*

7497. *The order anseres* comprehends the duck, goose, swan, and bussard. Under a regular system, Mowbray observes, it would be preferable to separate entirely the aquatic from the other poultry—the former to have their houses ranged along the banks of a piece of water, with a fence, and sufficiently capacious walks in front—access to the water by doors, to be closed at will. Should the water be of considerable extent, a small boat would be necessary, and might be also conducive to the pleasure of angling.

7498. *The duck* (*Anas boschas* L., fig 939.) is a native of Britain, and found frequenting the edges and banks of lakes in most parts of Europe. The flesh of this and various other species of the duck is savory and stimulant, and said to afford preferable nourishment to that of the goose, being less gross, and more easily digested. The flesh of the wild duck, though more savory than that of the tame, is reckoned still more easy of digestion. The ancients went even beyond our greatest modern epicures in their high opinion for the flesh of the duck, and Plinarch asserts, that Cato preserved his whole household in health by dieting them on duck's flesh.

7499. *Forcietes and specios*. There are the *Rhene*, the *Aythia*, the *canass-busket*, and the *Mal. covy*.

7500. *The Rhene duck* is originally from France, and generally of a dark-colored plumage, large size, and supposed to improve our breed. They are of farther flesh, and more savory than the English duck; but somewhat coarser. Rhene ducks have been so constantly imported from great numbers of years, that they are very generally mixed with our native breed. The English duck, particularly the white variety, especially when they choose to have light-colored flesh, are never of so

high and airy; it is the highest relation. Memory, and other faculties of the duck, are kept under out of curiosity than for the table.

7204. The only, apparently a beautiful, and ornamental duck, resembling well in colour with the Indian goose. They are said to be very brood.

7203. The Muscovy duck (*A. moschata* L.) is a native of Brazil, but domesticated in Europe. It is a curious dark-coloured bird, distinguished by its naked face, kept more out of curiosity than use to be retained in any place, they must be reared there from the egg, otherwise they will fly away.

7204. Brooding. One drake is generally put to five ducks. The duck will cover from eleven to fifteen eggs, and her term of incubation is thirty days. They begin to lay in February, are very prolific, and are apt, like the Turkey, to lay abroad, and conceal their eggs, by covering them with leaves or straw. The duck generally lays by night, or early in the morning. White and light-coloured ducks produce similar eggs; and the brown and dark-coloured ducks, those of a greenish blue colour, and of the argent size. In setting ducks, it is considered safest to put light-coloured eggs under light ducks, and the contrary. As there are instances of the duck turning out with her bill those eggs which were not of her natural colour.

7205. During incubation, the duck requires a secret and safe place, rather than any attendance, and will, at nature's call, cover her eggs, and seek her food, and the refreshment of the waters. On hatching, there is not often a necessity for taking away any of the brood, having accidents; and having hatched, let the duck rotate her young upon the nest her own time. On moving her with her brood, prepare a coop upon the shore grass, if the weather be fine, or under a shelter if otherwise. A wide and flat dish of water when to be renewed, standing at hand; barley or any meal, the first food. In rainy weather particularly it is useful to dip the tails of the ducklings, and the surrounding down beneath since they are also apt to draggle and weaken themselves. The duck should be cooped at a distance from any other. The period of her confinement to the coop depends on the weather and the strength of the ducklings. A fortnight seems the longest time necessary; and they may be sometimes permitted to enjoy the pond at the end of a week but not for too great a length at once, lest of all in cold wet weather which will sicken, and cause them to scour and appear rough and draggled. In such case they must be kept within a while, and have an allowance of bean or pea meal mixed with their ordinary food. The meal of buck-wheat and the farmer is then proper. The straw beneath the duck should be often renewed, that the brood may have a dry and comfortable bed. and the mother herself be well fed with solid corn, without an ample allowance of which ducks are not to be reared or kept in perfection, although they gather so much abroad.

7206. Duck eggs are often hatched by hens when ducks are more in request than chickens also as ducks, in unfavourable situations, are the more easy to rear as more hardy, and the plan has no objection in a confined place, and with a small stock, without the advantage of a pond, but the hen is much distressed, as is sufficiently visible and, in fact, injured, by the anxiety she suffers in witnessing the supposed perils of her children venturing upon the water.

7207. Ducks are fattened, either in confinement, with plenty of food and water, or full as well restricted to a pond, with access to as much solid food as they will eat. which last method is preferable. They fatten speedily in this mode, mixing their hard meat with such a variety abroad as is natural to them, more particularly if already in good case; and there is no check or impediment to thrive from pining but every mouthful tells and weighs its due weight. A dish of mixed food is preferable to white corn and may remain on the bank, or rather in a shed for the ducks. Barley in any form, should never be used to fatten ducks or geese, since it renders their flesh loose, woolly, and insipid, and deprives it of that high savour of brown meat, which is its valuable distinction. In a word, rendering it chickeny not unlike in flavour the flesh of ordinary and yellow legged fowls. Oats, whole or bruised, are the standard fattening material for ducks and geese, to which may be added pea-meal, as it may be required. The house-wash is preferable to mix up their food under confinement but it is obvious, whilst they have the benefit of what the pond affords they can be in no want of house food. Accents in season are much amused by ducks which have a range, and they will thrive so much on that provision, that the quantity of fat will be incoherent, both in cooking and upon the table. Ducks so fed are certainly inferior in delicacy but the flesh cuts high, and is far from disagreeable. Fed on butcher's offal, the flesh resembles wild fowl in flavour, with, however considerable inferiority. Offal-fed duck's flesh does not emit the abominable stench which issues from offal-fed pork. When live ducks are plucked, only a small quantity of down and feathers should be taken from each wing.

7208. Decoys for wild ducks. Wild ducks, and other aquatic birds, are frequently taken by the device termed a decoy, which, in the low parts of Essex and some other marshy districts, may be considered as connected with husbandry. A decoy is a canal or ditch provincially pike of water (fig. 340.) with a grassy

showing margin (1) at its junction with a river or larger piece of water (2) to invite aquatic fowls to sit on and draw their passages; but in other cases, covered with reeds and aquatic plants for concealment. Along the canal of the decoy are placed red decoys (3, 4) to conceal the decoy-man and his dogs from the sight of the ducks. There is an opening in this fence (5) where the decoy-man that shows himself in the birds to form them to take the water; and having taken it, the dog drives them up the canal, the man

looking through the fence at different places (4, 5, 6) to frighten them forward. At the end of the tunnel is a tunnel net (7), where the birds are finally taken. In operating with this trap, of the wild duck is a very shy bird, and delights in retirement, the first step is to endeavour to make the given water a peaceful asylum, by suffering the ducks to rest on it undisturbed. The same love of concealment leads them to be partial to waters whose margins abound with underwood and aquatic plants; hence, if the given water is not already furnished with these appendages, they must be provided. For it is not retirement alone which leads them into these recesses, but a search after food also. At certain times of the day, when wild fowl are off their feed, they are equally delighted with a smooth grassy margin, to adjust and oil their plumage upon. On the close-pastured margins of large waters, frequented by wild fowl, hundreds may be seen amusing themselves in this way and perhaps nothing draws them sooner to a water than a convenience of this kind; hence it becomes essentially necessary to success, to provide a grassy shelving smooth-shaven bank (3) at the mouth of the decoy in order to draw the fowl, not only to the water at large, but to the desired part of it. Having, by these means, allured them to the mouth of the decoy the difficulties that remain are, those of getting them off the bank into the water without taking wing and of leading them up the canal to the snare which is set for them in the most easy manner.

7510. In order to get them off the bank into the water a dog is necessary (the more like a fox the better) which should steal from behind the screen of reeds, (2, 2.) which is placed by the side of the canal to hide the decoy man as well as his dog, until the signal be given. On seeing the dog, the ducks rush into the water where the wild fowl consider themselves as safe from the enemy which had assailed them and of course do not take wing. Among the wild fowl, a parrot (perhaps eight or ten) of decoy-ducks should be mixed, which will probably be instrumental in bringing them, with greater confidence, to the bank. As soon as these are in the water they make for the decoy, the head of which they have been constantly fed, and in which they have always found an asylum from the dog. The wild ducks follow while the dog keeps driving behind and, by that means, takes off their attention from the trap they are entering. When as soon as the decoy man who is all the while observing the operation through peep-holes in the reed screen sees the entire shoal under a canopy net which covers and encloses the upper part of the canal, he shows himself when the wild fowl instantly take wing but their wings meeting with an imperious net, instead of a natural canopy formed of reeds and bulrushes, they fall again into the water and, being afraid to recede, the man being close behind them they push forward into the tail of the tunnel net, which terminates the decoy. In this way nine dozen have been caught at a time.

7510. The form of the pipe or canal ought to resemble the outlet of a natural brook, or a natural inlet or creek of the principal water. The mouth ought to be spacious, and free from confinement, that the wild fowl, on their first rushing into the water and while they have yet the power of recollection may be induced to begin to follow the tame ducks and for the same purpose it ought to be crooked, that its inward narrowness and the nets, may not, in the first instance be perceived. The lower part of a French horn is considered as the best form of the canal of a decoy that can be had. A material circumstance remains yet to be explained. It is the invariable nature of wild fowl to take wing with their heads towards the wind and it is always impudent to attempt to take them in a decoy unless the wind blow down the pipe for while their enemy is to forward of them, they have less scruple to go up the pipe, making sure of an escape by their wings. But, what is of still more consequence, if the wind set up the pipe when they take wing under the canopy net, some of them would probably escape (a circumstance always to be dreaded), and those which fell again into the water would fall, of course with their heads towards the wind and would with greater difficulty be driven into the tunnel. This point is as well known by decoy men in general, that every decoy is when circumstances will admit of it, furnished with three or four different canals pointing to a distinct quarter of the horizon, that no opportunity may be lost on account of the wind being in any particular point.

7511. The goose (*Anas Auser L.*, fig 941) is a native of Britain, and most parts of the north of Europe, but less common than the duck.

941

7512. The flesh of the common and various species of geese is highly stimulant, strong in flavour viscous, and of a putrescent tendency. The flesh of the tame goose is more tender than that of the wild which tastes of fish; but either kind is only adapted for good stomachs, and powerful digestion, and should be sparingly used by the sedentary and weak or persons subject to cutaneous diseases. The fat of the goose is reckoned peculiarly subtle penetrating, and testaceous, and is generally carefully preserved for domestic applications. The goose attains to a great age, well authenticated instances being on record to the extent of seventy and eighty years. The best geese in England are probably to be found on the borders of Suffolk and Norfolk, and in Berkshire but the greatest numbers are in Lincolnshire, whence they are sent in droves to London to be fed by the postillion some of whom fatten in the vicinity of the metropolis above five thousand in a season.

7513. Of varieties and species there are several the former differing in colour as black, white, and grey and also in size. There is also the Spanish white goose, and large white Embelian geese the latter in most respects. When one has seen a wild plumage will, to a feather exactly correspond with any other.

goose, says Pennant, a description of its but in the tame kinds no two of any species are exactly alike different in their size, their colours, and frequently in their general form, they seem the mere creatures of art and having been so long dependant upon man for support, they seem to assume forms entirely suited to his necessities.

7514. There is a Chinese species (*A. cygnoides*) and an American goose (*A. canadensis*). The Chinese species is a domestic bird but as yet little known in this country. It is longer and narrower in the body than the common goose, and stands higher on the legs. The Canadian goose is domesticated in several places, and is not considered uncommon in England. It is the most ornamental of the goose kind on water in pleasure-grounds, and is abundant in the Duke of Devonshire's park at Chiswick.

7515. Breeding. One gander is generally put to five geese the goose lays from eleven to fifteen eggs; and the period of incubation is from twenty-seven to thirty days. A nest should be prepared as soon as the female begins to carry straw in her bill, and by other tokens declares her readiness to lay. This is generally in March and sometimes two broods are produced within the season an advantage obtainable by high feeding through the winter with sound corn and on the commencement of the breeding season allowing them boiled barley malt, fresh grains, and fine pollard mixed up with ale or other stimulants. A good gander sits near his geese whilst they are sitting, and vigilantly protects them. Feeding upon the nest is seldom required; and it is unnecessary to take any of the goslings from the mother as hatched; but when the geese and her brood at once open dry grass well sheltered, putting them out late in the morning, or not at all in severe weather, and ever taking them in early in the evening. The first food may be similar to that recommended for the duck, such as barley meal, bruised oats, or fine pollard, with some scallion green vegetables, as cabbage or beet leaves intermixed.

7516. Rearing. At first setting at liberty the pasturage of the geese should be limited; otherwise, if allowed to range over an extensive common the pullets or goslings will become wild and straggled, and some of them will fall behind and be lost. Mowbray advises to destroy all the hemlock and nightshade in

their range, and he says he has known them killed by swallowing sprigs of yew. As the young become pretty well feathered, they become also too large to be brooded beneath the mother's wing, and as they will then sleep in groups by her side, they must be well supplied with straw beds, which they will convert into excellent dung. Being able, says Mowbray, to frequent the pond and range the common at large, the young geese will obtain their living, and few people favourably situated, allow them any thing more, excepting the vegetable produce of the garden. But it has been his constant practice always to dispense a moderate quantity of any solid corn or pulse at hand to the flocks of store geese, both morning and evening, on their going out and their return, together in the evening more especially with such geese as chance to be at command. Cabbage, mangel wurzel leaves, lucerne, tares, and occasionally sliced carrots. By such full keeping his geese were ever in a fleshy state, and attained a large size, the young ones were also forward and valuable breeding stock. Geese managed on the above mode will be speedily fattened green, that is, at a month or six weeks old, or after the run of the corn stubbles. Two or three weeks after the latter must be sufficient to make them thoroughly fat. A goose fattened entirely on the stubbles is to be preferred to any other, since an over-fattened goose is too much in the oil-skin and greasy tub style, to admit even the ideas of delicacy, tender firmness, or true flavour, but when needful to fatten them, the feeding houses already recommended for hens (747) are most convenient. With clean and renewed beds of straw plenty of clean water oats, crushed or otherwise pea or bean meal (the latter, however coarse and ordinary food or pollard mixed up with skim milk geese will fatten pleasantly and speedily).

7517. *Feathers*. Pennant, in describing the methods used in Lincolnshire in managing geese, says, "They are plucked five times in the year—first at Lady-day for the feathers and quills and four times for the feathers only, between that and Michaelmas." He says, he saw the operation performed on goslings of six weeks old, from which the feathers of the tails were plucked, and that numbers die of the operation, if the weather immediately afterwards proves cold. "This seems a cruel practice and surely would be better left off." Lean geese furnish the greatest quantity of down and feathers, and of the best quality.

7518. *The mute or tame swan* (*Cygnus mansuetus* L. *fig* 942) has long been known

occasionally affording cygnet and some swan down feathers and quills. It is a curious circumstance that the ancients considered the swan as a high delicacy, and abstained from the flesh of the goose as impure and indigestible.

7519. *Other species are, first, the swan goose* (*A. cygnoides* L.). This is of an intermediate size between the tame swan and the common goose, with the last of which they will breed, and although they vary considerably in their colour, the species is always given by a knob on the bill. The two others which have been domesticated with us are the Canadian and the Egyptian species. The first is equally valuable with the common goose, and is very ornamental in ponds: the latter is now become very rare. The black swan, once considered a prodigy, is abundant in various parts of New Holland or Australia.

7520. *Rearing*. The swan feeds like the goose and has the same familiarity with its keepers, kindly and eagerly receiving bread which is offered, although it is a bird of courage equal to its apparent pride, and both the cock and hen are extremely dangerous to approach during incubation, or whilst their brood is young, as they have sufficient muscular force to break a man's arm with a stroke of their wing. They both labour hard in forming a nest of water plants, long grass and sticks generally in some retired part or inlet of the bank of the stream or piece of water on which they are kept. The hen begins to lay in February, producing an egg every other day until she has deposited seven or eight on which she sits six weeks, although Buffon says it is nearly two months before the young are excluded. Swans eggs are much larger than those of a goose white and with a hard and sometimes tuberculous shell. The cygnets are ash coloured when they first quit the shell and for some months after, indeed they do not change their colour nor begin to moult their plumage, until twelve months old, nor assume their perfect glossy whiteness until advanced in their second year.

7521. *Feathers and down*. Where the living swan is plucked, only the ripe down should be taken from each wing, and four or five feathers. This may be repeated to the extent of three times in the course of a summer.

7522. *The bustard* (*Otus tarda* L. *fig* 943) is a native of England, the largest indigenous land bird in Europe, the cock generally weighing from twenty five to twenty-seven pounds. The neck a foot long, the legs a foot and a half. It flies with some little difficulty. The head and neck of the cock ash-coloured, the back barred transversely with black and bright rust colour. The greater quill feathers black, the belly white, the tail, consisting of twenty feathers, marked with broad black bars. It has three thick toes before, and none behind.

7523. *Three species of bustard are found in England, that called the little bustard* (*O. tetrax*) differs chiefly in size, not being larger than a pheasant. Bustards were known to the ancients in Africa, and in Greece and Syria are supposed to live about fifteen years, are gregarious, and pair in spring, laying only two eggs, nearly of the size of a goose egg, of a pale olive brown, marked with spots of a darker hue. They sit about five weeks, and the young ones run, like partridges, as soon as detached from the shell. The cocks will fight until one is killed or slain. Their flesh has ever been held most delicious; they are

fed upon the same food as the turkey. There were formerly great flocks of bustards in this country upon the wastes and in the woods, particularly in Norfolk, Cambridgeshire, and Dorset, and in various parts of Scotland, where they were hunted with greyhounds, and were easily taken. Buffon was mistaken in his supposition that these birds are incapable of being propagated in the domestic state, chiefly on account of the difficulty of providing them with proper food, which in their wild state, he describes to be heath-berries and large earth-worms. Probably the haw or whitethorn berry might succeed equally well. To those who aim at variety and novelty in this line, the bustard appears peculiarly an object for propagation and increase, since the flesh is of unrivalled excellence; and it is probable this fowl will render great weight of flesh for the food consumed.

#### SECT. IV. Diseases of Poultry

7524. *The diseases of poultry* are generally the result of improper nourishment and lodging and the best mode of cure is by the immediate adoption of such as is proper. When that will not succeed, very little help can be derived from medical assistance; at least as that art stands at present with respect to poultry. In fact, as Mowbray observes, the far greater part of that grave and plausible account of diseases to be found in our common cattle and poultry books is a *sarrago of absurdity* the chief ground of which is random and ignorant guess-work.

7525. *Common fowls* are attacked by the pip, roup or catarrh the flux, constipation, and vermin. The pip is an outsize skin or scale growing on the tip of the tongue, and is cured by teasing of the skin with the nail and rubbing the tongue with salt. Imposthume on the rump is called the roup, which term is also applied to catarrh, to which gallinaceous fowls are very subject. The imposthume is to be opened, the core thrust out, and the part washed with salt and water. Generous food and warmth is the only cure in the catarrh. The flux is to be cured with good solid food and its opposite constipation, with scalded bran mixed with skim-milk or pot liquor adding a small quantity of sulphur. Vermin appear in consequence of low keep and want of cleanliness the simplest remedy is to allow plenty of sand and ashes for the birds to roll in and to keep their houses and roosts sweet and clean while-washing them two or three times a year.

7526. *The roup* is a very common, and one of the most fatal complaints to which chickens are subject. Those attacked by the disease are constantly coughing and gasping for breath. Upon dissection the wind-pipe is found almost closed up by great numbers of small red worms, which, in a certain stage of their growth congregate into bundles large enough to stop respiration and which if the sufferer cannot discharge at the mouth, soon produces suffocation. Devotions of the common yellow *Linna vulgaris* (Zorr. Avs. 12645) is given as drink which being nauseously bitter is supposed offensive to the worms but perhaps some mercurial preparation taken inwardly or applied outwardly would answer the purpose, and, if effectual, would save thousands of chickens every year. This suggestion has never been tried.

7527. *But the catarrh* is the chief disease to which chickens and fowls are liable; and when the malady becomes confirmed with running at the nostrils, swollen eyes, &c. they are termed roup and the disease is infectious. They should now be separated and kept in a warm apartment and well fed. Roupish hens seldom lay and their eggs are unwholesome. In chickens this disease is called the chip they are seen shivering pining and dying in corners, apparently from cold, though they are in fact in a fever. Abundant warmth and rich food are the only remedies.

7528. *Broken legs, wings or toes* may be set and splined, and will recover the head being raw and the eyes blinded from fighting wash the eyes with milk and water and the head alternately with brandy in which is a few drops of laudanum and with fresh butter. A cock's spurs being too long, impeding his walk and wounding his legs they should be cut carefully with a sharp pen knife but not too near the joint, every three months.

7529. *Geese* are subject to the pargle or stoppage in the head, the consequence of cold. House the patient, and give garlic beat up with fresh butter or toset and ale with a little confinement, will succeed equally well.

7530. *All poultry* when young, are apt to be carried off by rats and other vermin which must either be vigilantly guarded against or destroyed.

#### SECT. V. Birds of Luxury which are or may be cultivated by Farmers.

7531. *Birds of luxury* are the pigeon, pheasant, partridge, quail, grouse, singing birds, and birds kept as curious objects.

7532. *Of the pigeon* (*Columba L.*) there are three species and many varieties in cultivation. The species are the common, ring and turtle doves, all natives of Britain. The varieties of the common pigeon enumerated by Linnæus amount to twenty-one but those of the pigeon-fanciers to more than double that number. The ring-dove (*C. Palumbus L.*) and the turtle-dove (*C. Turtur*), with the greater number of the varieties, are cultivated only by a few persons, known as pigeon-fanciers but the common pigeon of different colours is cultivated for the table.

7533. *The flesh* of the young pigeon is very savoury and stimulating and highly valued for pies that of the full-aged pigeon is more substantial, harder of digestion and in a considerable degree heating. Black or dark feathered pigeons are dark fleshed and of high flavour inclining to the game bitter of the wild pigeon. Light-coloured feathers denote light and delicate flesh. The dung of pigeons is used for tanning upper leathers for shoes; it is also an excellent manure. Pigeons are now much less cultivated than formerly being found injurious to corn fields, and especially to fields of peas; they are, however, very ornamental. A few may be kept by most farmers, and fed with the common poultry and some who breed domestic fowls on a large scale may perhaps, find it worth while to add the pigeon to their number.

7534. *The variety of pigeon* most suitable for the common pigeon house is the grey pigeon (fig. 944.) inclining to ash-colour and black, which generally shows fruitfulness by the redness of the eyes and feet, and by the ring of gold about which is about the neck.

7535. *The varieties* of the fancy breeders are numerous, and distinguished by a variety of different names, as carriers (fig. 944. a) croppeers, powder, horsemen, ruffs, jacobins, turtles, henners, nuns, tumblers (b) barbs, popes, owls, gods, trumpeters, shakers, crows, skinks, &c. From these, when differently paired, are bred bastard pigeons; thus from the cropper or powder and the carrier is bred the powling horseman (c); from the tumbler and the horseman dragonet, &c.

1796. The shooting of pigeon-beans is best performed in May or August, as the birds are then in the best condition. Young birds called squabs should be chosen, as the old are apt to fly away.

945

1797. In breeding, the pigeon lays two white eggs, which produce young ones of different sexes. When the eggs are laid, the female sits fifteen days, not including the three days she is employed in laying; and is relieved at intervals by the male. The parents are generally pretty regular. The female usually comes from about five to the evening till nine the next morning, at which time the male supplies her place, while she is seeking refreshment abroad. Thus they sit alternately till the young are hatched. If the female does not return at the expected time, the male seeks her, and drives her to the nest; and should he in his turn be neglectful, she retaliates with equal severity. When the young ones are hatched, they only require warmth for the first three days; a task which the female takes entirely upon herself, and never leaves them except for a few minutes to take a little food. After this they are fed about ten days, with what the old ones have picked up in the field, and kept treasured in their crops, from whence they satisfy the craving appetite of their young ones, who receive it very greedily. This way of supplying the young with food from the crop, in birds of the pigeon-kind, differs from all others. The pigeon has the largest crop of any bird, for its size, which is also quite peculiar to the kind. In two that were dissected by an eminent anatomist, it was found that, upon blowing the air into the windpipe, it distended the crop or gullet to an enormous size. Pigeons live entirely upon grain and water, these being mixed together in the crop are digested in proportion as the bird lays in its provision. Young pigeons are very voracious, which necessitates the old ones to lay in a more plentiful supply than ordinary and to give it a sort of half mastication in the crop, to make it fit for their tender stomachs. The numerous glands, saturated by air and the heat of the bird's body, are the necessary apparatus for secreting a sort of pap, or milky fluid (commonly called pigeon's milk); but as the food masticates, it also swells, and the crop is considerably dilated. If the crop were filled with solid substances, the bird could not contract it; but it is obvious the bird has the power to compress its crop at pleasure, and, by discharging the air can drive the food out also, which is forced up the gullet with great ease. The young usually receive this tribute of affection from the crop three times a day. The male for the most part feeds the young female, and the old female performs the same service for the young male. While the young are weak, the old ones supply them with food masticated suitable to their tender frame; but, as they gain strength, the parents give it less preparation, and at last drive them out, when a craving appetite obliges them to shift for themselves; for when pigeons have plenty of food, they do not wait for the total dissipation of their young, it being a common thing to see young ones fagged, and eggs hatching at the same time and in the same nest.

1798. The service applied to pigeons of different ages are, the youngest, when fed by the cock and hen, squabs, at which age they are most in demand for pies. Under six months of age, they are termed squabblers; at that age they begin to breed, and then or earlier they are in the fittest state for removal to a strange situation.

1799. In respect to food pigeons are entirely granivorous, and very delicate and cleanly in their diet; they will sometimes eat green aromatic vegetables, but are fond of seeds; and tares, and the smallest kind of horse-beans, is the most suitable food both in point of economy and fattening qualities. Peas, wheat, buck-wheat, and even barley oats, &c. are also eaten by pigeons, but old tares may be reckoned their very best food; new tares, peas, or beans, are reckoned scouring. Wherever pigeons are kept, the best way to keep them chiefly at home, and thereby both prevent their being lost, and their doing injury to corn-crops, is to feed them well; this is also the only way in which in modern times, they will afford abundance of fat and delicate squabs for the table, which, well fed they will do every month in the year and thus afford a constant supply of delicate stimulating food. Pigeons are generally fed in the open air adjoining their coops or houses; but in inclement weather or to attach new pigeons to their house both food and water should be given internally. That this may be done without waste, and without frequently disturbing the birds, two contrivances are in use: the first is the meat-box or hopper from whence grain or pulses descends from the hopper as eaten out of a small shallow box; the next is the water-bottle, an ovate, long, naked bottle, reversed in a small basin to which it serves as a reservoir. Any bottle will do, but the pigeons are apt to alight on and dirty such as when reversed present a flat top.

1800. Pigeons being fond of salt what is called a pigeon cut is placed in the midst of the pigeon-house or in the open air near it. It seems these birds are fond of salt and hot substances, and constantly swallow small stones to promote digestion. The salt-cut is thus composed. Gravel or drift-sand, unctuous loam, the rubbish of an old wall, or lime a gallon of each (should lime be substituted for rubbish, a less quantity of the former will suffice) one pound of common-salt, one hundred of bay-salt mix with stale urine. Inclose this in jars, corked or stopped, holes being punched in the sides, to admit the beaks of the pigeons. These may be placed abroad. They are very fond of this mixture, and it prevents them from pecking the mortar from the roofs of their houses, which they are otherwise very apt to do.

1801. Cleanliness is one of the first and most important considerations: the want of it is a dove-note will soon render the place a nuisance not to be approached and the birds, both young and old, will be so covered with vermin, and beset with their own excrement, that they can enjoy no health or comfort, and mortality is often so induced. Bowtrays should be cleaned daily (thoroughly once a week a tub standing at hand for the reception of the dung, the floor covered with dried gravel often renewed).

1802. Pigeon-houses are of three kinds, small boarded cases fixed on posts, trees or against the ends of houses; lofty siting up with holes or nests and detached buildings. The first are generally too small to contain a sufficient brood, and are also too subject to variations of temperature; and the last, on the other hand, are now-a-days too large, and therefore the most suitable for the farmer is a loft or tower rising from a building, in which no noisy operation is carried on. The lofts of any of the farm-buildings at a distance from the threshing machine are suitable, or a loft or tower over any detached building, or if narrower well; but the best situation of all is a tower raised from the range of poultry-buildings, where there is such a cage as the pigeons can thus be more conveniently treated, and will feed very readily with domestic poultry. For a tower of this sort, the round form should be preferred to the square, because the rats cannot so easily come at them in the former as in the latter. It is also much more commodious, as, by means of a ladder turning round upon an axis, it is possible to visit all the nests in the house, without the least difficulty; which cannot be so easily done in a house of the square form. And in order to hinder rats from climbing up the outside of it, the wall should be covered with tin-plates to a

certain height, as about a foot and a half which should project out three or four inches at the top, supported their getting up more gradually. A common mode in France is to raise a boarded room on a strong post powerfully fixed (Fig. 946), the interior sides of which are lined with boxes for the birds (a) and the exterior east and west sides with balconies, or sills for them to alight on and enter their boxes (b). The north and south sides are lined with better boxes, but without openings, as being too cold on the one front, and too warm on the other.

946. The interior of the pigeon-house must be lined with nests or boxes subdivided either by stone, as in the ancient mural pigeon-houses by boards or each nest composed of a vase or vessel of earthenware fixed on its side. Horizontal shelves (Fig. 947) divided vertically at three feet distance are generally considered preferable to every other mode; the width of the shelf may be twenty inches, the height between shelf and shelf eighteen inches and a slip of board three or four inches high is carried along the front of the partitions to keep in the nests. Sometimes, also, a partition of smaller height is fixed in the middle of each three-foot division, which thus divides it into two nests. This Mr. Bray and Girtton concur in recommending as likely to prevent the young from running to the hen when sitting over fresh eggs, and perhaps constituting her to cool and addle them. For when the young are about a fortnight or three weeks old, a good hen will leave them to the care of the cock and fly again. Some prefer breeding holes with no board in front, for the greater convenience of cleaning the nests; but as the squabs are apt to fall out by this practice, a good way would be to contrive the board in front to slip up and down in a groove, by which each nest might be cleaned at pleasure. As tame pigeons seldom take the trouble of making a nest, it is better to give them one of hay to prevent the eggs from rolling. There are also straw buckets made in the form of nests, and also nests or pans of earthenware. Where pans are used, it is common to place a brick between them (two being placed in a breeding hole) for the cock and hen to alight on; but on the whole straw nests are best. The pigeon house has two entrances one a common sized door for man, either on the ground level or to be ascended by a ladder as used formerly to be the case, and the other on a range above the roof and consisting of small holes three or four by twelve or fourteen inches, for the entrance of the pigeons. A series of ranges of these are generally placed over each other in a boarded front looking to the south with a shelf to each range, and surrounded by a row of iron spikes to protect them from cats. The elevation of pigeon houses (Fig. 948) as already described are of endless variety.

948. The breeding holes constitute the fixtures of the pigeon-house its windows are the boxes and bottle already described (Fig. 949) a barrel or box for food, a step ladder to reach the nests, and some other articles not peculiar to this department of rural economy. The pigeon trap, for catching and entrapping the pigeons of others, we do not describe.

949. Pigeons in new lodgings are apt accustomed to forsake their habitations. Many notions have been recommended to prevent them from doing so but if squabs be selected cleanliness and security attended to, and a salt cot placed in or near the house there will be little danger of this taking place. Fumigation with highly odorous drugs, or even asafoetida, is also said to attract pigeons to a neglected dove-cote, or attach them to a new one.

950. Diseases of pigeons. Fancy pigeons, being many of them monstrous productions, are very subject to diseases. Girtton enumerates upwards of a dozen with their cures, including the corruption of the egg in the uterus from over high feeding, a gorged crop from voracious feeding insects from stinkiness in the pigeon house, and the canker from cocks fighting with each other. Little can be done in the way of curing any of these diseases other wise than by recurrence to the proper regimen. If this does not speedily take effect, it is better to put the bird *hors de paille* both for humanity's sake and to prevent infection. Fortunately the common pigeon raised for the table is little liable to diseases.

951. Laws respecting pigeons. By the 1st of James, c. xxvi. shooting, or destroying pigeons by other means, on the evidence of two witnesses, is punishable by a fine of 50s. for every bird killed or taken, and by the 3d of Geo. III. c. xxix. the same offence may be proved by one witness, and the fine is 20s. to the prosecutor. Any lord of the manor or freeholder may build a pigeon-house upon his own land, but a tenant cannot do it without the lord's licence. Shooting or killing within a certain distance of the pigeon-house renders the person liable to pay a forfeiture.

952. The common pheasant (*Phasianus colchicus L.*) is a native of the old continent, but not of America, and has long been naturalised in the warmer and most woody counties of England. It is very common in France, and before the Revolution used to be a great nuisance to the farmers, even to the gates of Paris. The pheasant runs fast, but flies low and heavily. It crows not unlike the common cock, being of the same genus, and is supposed to live six or eight years.

953. Pheasants are both *granivorous* and *carnivorous* they feed upon all sorts of insects and vermin like the peacock, and are said to be greedy of toads when not too large to swallow, whereas, according to report, they will not touch the frog of which ducks are so fond. They are prized in park scenery for their beautiful plumage and showy figure, and as game for the delicacy of their flesh, which is of a high savour and alkaliescent quality. It is in season in autumn, and most esteemed when under a year old, and very fit. Every gentleman who has a well wooded, well enclosed park, and in whose woods are abundance of such evergreens as the spruce fir holly box, broom, &c. may stock it with pheasants and he may preserve his stock if he will continue to supply them with abundance of food, and deter thieves, polecats, &c. The more common the pheasant becomes, the less will it be subjected to the attacks of these enemies.

**7500. Pheasants.** Besides that which may be considered common or wild in this country and which is generally of a brown colour, there is the gold and silver natives of China, and very hardy in this country and good breeders. The ring-neck, natives of Tataria bred in China, very scarce; their plumage very beautiful. The white and pied, both sorts will intermix readily with our common breed, as will the Bohemian, one of the most beautiful of its kind, and equally scarce. The golden variety is generally of the highest price, and the common most hardy and of the largest size.

**7551. Breeding.** In a wild state the hen pheasant lays from eighteen to twenty eggs in a season, but seldom more than ten in a state of confinement. As this bird has not hitherto been domesticated, and as the flesh of those brought up in the house is much inferior to that of the wild pheasant, they are chiefly bred for show for replenishing a park, or for turning out in well enclosed reserves some, which they will not readily leave if well fed, and not much disturbed. Scarce every proprietor may naturalize them at least on a part of his grounds. For example, a wood with glades of pasture enclosed by a close paling or high wall. The natural instinct of the pheasant is to feed on the ground and composed of dry grass and leaves, which being provided for her in confinement, she will always arrange properly. They will breed freely with the common fowl but as neither flesh nor form are improved by the cross, this is seldom resorted to.

**7552. In stocking a pheasantry,** the general mode is to procure eggs from some establishment of this sort or otherwise; and the following are the directions of Castane, as given in *Mowbray's Treatise on Poultry*.—Eggs being provided, put them under a hen that has kept the nest three or four days; and if you set two or three hens on the same day you will have the advantage of shifting the good eggs. At the end of ten or twelve days, throw away those that are bad and set the same hen or hens again, if setting-hens should not be plenty. The hen having set their full time such of the young pheasants as are already hatched put into a basket, with a piece of flannel, till the hen has done hatching. The brood now comes, put under a flame with a net over it, and a place for the hen, that she cannot get to the young pheasants, but that they may go to her and feed them with boiled egg cut small, boiled milk and bread, alum curd, and eggs, a little of each sort, and often. After two or three days they will be acquainted with the call of the hen that hatched them, may have their liberty to run on the grassplot, or elsewhere, observing to shift them with the sun, and out of the cold winds; they need not have their liberty in the morning till the sun is up, and they must be shut in with the hen in good time in the evening. Every thing now going on properly you must be very careful (in order to guard against the distemper to which they are liable) in your choice of a situation for breeding the birds up and be less afraid of foxes, dogs, polecats, and all sorts of vermin, than the distemper. Castane had rather encounter all the former than the latter for those with care may be prevented, but the distemper once got in is like the plague, and destroys all your hopes. What he means by a good situation is nothing more than a place where no poultry pheasants, or turkeys, &c. have ever been kept; such as the warm side of a field, orchard, pleasure-ground, or garden, or even on a common, or a good green lane under circumstances of this kind or by a wide side but then it is proper for a man to keep with them, under a temporary hovel, and to have two or three dogs chained at a proper distance, with a lamp or two at night. He has known a great number of pheasants bred up in this manner in the most exposed situations. It is proper for the man always to have a gun, that he may keep off the hawks, ewis, jays, magpies, &c. The dogs and lamps why the foxes more than any thing; and the dogs will give courage for the man to be on his guard if smaller vermin are near or when drovers make their appearance. The birds going on as before mentioned, should so continue till September, or (if very early bred) the middle of August. Before they begin to shift their long feathers in the tail, they are to be shut up in the basket with the hen regularly every night and when they begin to shift their tail the birds are large, and begin to lie out that is, they are not willing to come to be shut up in the basket those that are so should be taught to perch (a situation they have never been used to) this is done by tying a string to the hen's leg, and obliging her to sit in a tree all night be sure you put her in the tree before sunset and if she falls down, you must persevere in putting her up again till she is contented with her situation then the young birds will follow the hen, and perch with her. This being done, and the country now covered with corn, fruits and shrubs, &c. they will shift for themselves. For such young pheasants as you make choice of for your breeding-stock at home and elsewhere to turn out in spring following provide a new piece of ground, large and rocky for two perches where no pheasants, &c. have been kept and there put your young birds in as they begin to shift their tails. Such of them as you intend to turn out at a future time, or in another place, put into one pen netted over and leave their wings as they are, and those you wish to keep for breeding put into the other pen, cutting one wing of each bird. The gold and silver pheasants you must pen earlier or they will be off. Cut the wing often, and when first penned feed all your young birds with barley-meal, dough corn and plenty of green turpney.

**7553. A receipt to make alum curd.** Take new milk, as much as your young birds require, and boil it with a lump of alum, so as not to make the curd hard and tough, but custard-like. Give a little of this curd twice a day and some eggs after every time they have had a sufficient quantity of the other food. If they do not eat heartily, give them some ants eggs to create an appetite, but by no means in such abundance as to be considered their food. The distemper alluded to above is not improbably of the same nature as the roup in chickens, contagious, and dependent on the state of the weather and for prevention requiring similar precautions. When a pheasantry is connected with a piece of ground covered with bushes or shrubbery the birds may be bred in houses or pens, and afterwards put out into small enclosures, say one hundred feet square with fences twelve feet high, each containing abundance of low evergreens, especially the spruce fir and an artificial or natural supply of water. Under such an arrangement the hen pheasant will hatch her own eggs, and the following directions are given as to attendance by the same experienced person.—Not more than four hens to be allowed in the pen to one cock. And in the out-courts, three hens to one cock may be sufficient, with the view of allowing for accidents, such as the loss of a cock or hen. Never put more eggs under a hen than she can well and closely cover the eggs fresh and carefully preserved. Short broods to be joined and shifted to one hen. Common hen pheasants in close pens, and with plenty of cover will sometimes make their nests and hatch their own eggs but they seldom succeed in rearing their brood being so naturally shy, whence, should this method be desired, they must be left entirely to themselves, as they feel alarm even in being looked at. Eggs for setting are generally ready in April. Period of incubation, the same in the pheasant as in the common hen. Pheasants, like the pen-fowl, will clear grounds of insects and reptiles, but will spoil all wall-trees within their reach, by picking off every bud and leaf.

**7554. Feeding.** Strict cleanliness to be observed, the most not to be tainted with dung, and the water to be pure and often renewed. Ants eggs being scarce, beg lice, ear-wigs, or any insect may be given; or artificial nests seen substituted, composed of flour broken up with an egg and shell together, the pellets rubbed between the fingers to the proper size. After the first three weeks, in a scarcity of ants eggs, Castane gives a few gentles, procured from a good liver tied up, the gentles when ready dropping into a pan or box of bran; to be given sparingly and not considered as common food. Food for grown pheasants, barley or wheat; generally the same as for other poultry. In a cold spring hempseed, or other warming seeds are considerable, and will forward the breeding stock.

**7555. In keeping fancy pheasants,** as the gold, silver, or other breeds, the best mode is to enclose a few poles of ground containing trees and bushes with a well painted copper netting, and in some concealed part to have a house or lodge for supplying water and food. This forms by far the most elegant aviary and is the only one that at all times appears clean. They will thrive very well, however in an aviary on the common construction.

7556. The partridge (*Tétrao Perdrix*, fig 949.) is a native of all the temperate regions of Europe, but unable to sustain rigorous cold or intense heat.

7558. The quail (*Tétrao Coturnix*, fig 950.) is a native of the East, and abounds in Egypt, as appears from the supplies the Israelites obtained while in the wilderness, and also in the islands of the Archipelago, and in Italy. They migrate from warmer to colder regions. They are naturalised and breed in England, changing their residence within it on the approach of winter from the more exposed to the more temperate districts. They are very abundant in France, and are caught in snares and nets

(described by Roemer), and sent both to the Paris and London markets. The bird was

proverbial among the Romans as capacious and quarrelsome, and is employed among the Chinese for the same amusement as game cocks are in England. Here it is not domesticated, but may be reared and preserved in the same manner as the pheasant and partridge, and its food is nearly the same as that of the latter bird.

7559. The red grouse or moor cock (*Tétrao scoticus*, fig 951) is an esteemed variety of *Gallinacea*, pursued with avidity by sportsmen in the mountainous districts of England, Wales, and Scotland in which latter it abounds, there feeding in plenty among the heather, its favourite food. Its beautiful plumage and its exquisite flavour, render it an object of considerable interest.

7560. The black grouse or black cock (*Tétrao Tétrix*, fig 952.) is less common than the red grouse, and is therefore more highly prized. It is also larger weighing nearly four pounds. Its plumage is a rich mixture of black with blue, relieved by marking of white. Its legs are also covered with very fine minute feathers and it draws a peculiar characteristic from the curvilinear form of the tail, which branches out at the end into two crooked expansions. In wet seasons a great mortality is frequently observed among the grouse from intestinal worms.

7561. The wood grouse or cock of the wood (*Tétrao Urogallus*, fig 953), is, after the bustard the largest bird among those we call game. It being little less than a turkey. It was originally common in the mountainous parts of Britain but is now nearly if not wholly extinct with us though still common in the northern parts of Europe, where it lives in pine forests, on the cones of which it is supposed to subsist, and which at some seasons gives its flesh a terebinthinated taste at other times it is delicious eating, and is often sent to England frozen. Like the other grouse, he has the scarlet patch on his head, his legs are defended in the same manner by a feathered covering, and his whole markings are equally varied and beautiful. From the richness of the plumage in all the varieties of the *Tétrao*, and from the extreme delicacy of their flesh as

an article of food, it is to be lamented that attempts are not made to domesticate them in addition to our other poultry. It is thought by observant sportsmen and scientific naturalists, that this might be attended with less difficulty than the domesticating the partridge and pheasant and the attempt is recommended to the patriotic amateur.

7562. The lark (*Alauda arvensis* L.) and other birds were reared and fattened by the Romans for the table. The lark is caught by nets and other means in some of the open districts of England, as about Dunstable, Cambridge, &c., and brought to market for the table, as are various other birds by a particular class of men known as bird-catchers. It is an idle uncertain kind of life not to be recommended.

7563. *Of singing birds, a great variety are domesticated; and their breeding and rearing forms a very peculiar and curious branch of rural economy. Not only all the birds which please by the natural song are domesticated and kept in cages, as the canary, nightingale, lark, linnet, finch, thrush, &c.; but even some which do not sing in a wild state, as the sparrow, bawmer, &c., are by art taught the notes of other birds.*

7564. *While singing birds are caught by various devices, according to the species of bird and season of the year. The pairing season is spring, generally March and April, is on the whole the best season, and the common means are a net called a clip-trap; a bird of the species to be caught, called a call-bird, to attract the wild one; and another a female, called a house-bird. Bird-time is also very generally used; and for nightingales, a small hole dug in the ground covered with a perforated board, or a small round spring trap, called a nightingale trap, is resorted to. Glasses called larkers are used to call larks, and hawks are used to frighten some species, to render them more readily taken. As it is only the male birds which sing, or at least are of any value for their song, it is a very material part of the bird fancier's art to know the male from the female when they are both young; in general he is larger and longer.*

7565. *In breeding and rearing some birds the chief art consists in teaching them to sing. This is fre-*

quently done by the human voice alone, but more commonly by the aid of the flageolet or a small barrel organ. The organ is used in Germany in teaching the nightingale-notes to the canary and in teaching regular tunes, as marches, waltzes, &c. to the bullfinch which after being so taught are called piping bullfinches, and cost from £1. to 7 or 8 guineas each in London. In Italy the canary is taught various notes and tunes by the flageolet. In France, and also in this country one bird is taught by another being placed in a cage near it. When not taught at all, and not within the hearing of other birds, each bird utters its natural notes but very imperfectly. In general they are more ready to imitate the note of any bird they hear even of a hen or duck, than to utter those which are natural to the species. This certainly appears singular, but it is a well known fact.

7566. *The aviary, or place for breeding and keeping singing birds, may be a long narrow apartment fronting the south the front to be covered with wire netting, and within this glass cashes which may be removed in summer. There should also be a slot in the door or back wall to supply heat in cold weather. In such a building various birds may be kept in cages, or a few sorts in compartments. Thus a considerable space may be allotted to the breeding of the canary, for which there is the greatest demand. The next largest to the linnet and nightingale and any others may be kept in cages. Indeed, singing birds are invariably found to sing best when kept in separate cages, and apart from each other. In gardens or pleasure-grounds these cages may be suspended from trees, or supported by light iron props (figs. 954, 955.) and those who would wish to pursue this branch, either as one of amusement or profit, will find ample instructions in *Treatises of Bird Fancier* and other similar works.*

7567. *Foreign aquatic birds may be kept in the artificial waters of pleasure-grounds by shortening the feathers of one wing, and without any other care than a duck-house or shelter during night.*

7568. *The training of hawks and other birds for hunting of decoy birds of different sorts, as ducks, singing birds, pigeons, &c. belongs more to sportsmanship than agriculture, and may be learned in *Daniel's Rural Sports*, and various old books, such as *The Country Gentleman's Recreation*, &c.*

## CHAP. X.

### *Fish and Amphibious Animals subjected to Cultivation.*

7569. *The cultivation of fish is carried on to a very limited extent in Britain, owing to the great superiority of the sorts obtained by fishing in rivers or the sea, and to the decline of the catholic religion, which no longer renders fish an article of importance on certain days and seasons. However, in a few places fish are bred and reared for the market, and in gentlemen's grounds in the interior of the country some attention is generally paid to stocking the ornamental pieces of water with appropriate fish. Bakewell, in his instructive *Treatise on the Trout*, suggests the idea of introducing exotic fish and naturalising them in our lakes and rivers, and he mentions some Swiss species that he thinks would be particularly valuable. In the *Edinburgh Review* for 1833, is a curious paper on the possibility of rearing sea-fish in our fresh water lakes. See also *Brande's Quarterly Journal*, Nov. xxxii. and xxxiv. It appears that the flounder and the mullet have been naturalised to fresh water and that it is probable the whole of the fishes of analogous habits, and particularly those of the genus *Pleuronectes*, might be habituated to inland lakes.*

7570. *The mode of constructing ponds for retaining water for general purposes has been already described (446.) Ponds, especially for the purpose of breeding and rearing fish are formed at least in deep valleys, and slight depressions between hills, where there are rivers or waters; and*

different ones may often be made on the same line, the head of one constituting the bottom of that above it. The extent of them must be regulated by the nature of the situation, and the supplies of water that can be procured. In situations of this nature, the principal expense consists in constructing the heads or heads across the valleys, for keeping up the waters, and providing them with suitable sluices, which, where the land is of the loamy or clay kind, may be cheaply effected in the manner that earth works are usually performed. The foundations being laid sufficiently deep, and the earthy materials well applied by proper puddling and ramming, in the way of making embankments. The heights and strength of the dams or heads being regulated by the nature of the situations, and the quantity of water that is to be dammed up. The sluices should be the greatest which are next the waters. There must also be diverting channels for taking off the superabundant waters in the time of floods, which may be formed along the sides the sluices being placed in the lowest parts, and being well made of seasoned oak, and tightly rammed in with the earthy materials. Detailed instructions on this subject will be found in the *Quarterly Journal of Agriculture*, vol. i. p. 267.

7571. *Sea water fish-ponds* are unknown on the Continent, and not common in England. In Scotland, however there are several, which are stocked chiefly with turbot, cod, haddock, whiting, thornback, sea-bass, and salmon. One of the largest and best of these fish ponds is that of Macdonnell of Laggan, in Wigtownshire, which has been in existence for upwards of thirty years. (*Macdonnell's Sketches from Nature and Highland Soc. Trans.* vol. vii. p. 267.)

7572. The kinds of fish adapted for ponds are chiefly the carp, tench, perch, gudgeon, eel and pike.

7573. The carp (*Cyprinus Carpio* L. fig 956. a) is by far the best fish for artificial management, and especially that variety known in England as the Prussian carp. Carp inhabits the slow and stagnant waters of Europe and Persia, and was introduced into Britain in the year 1614, about four feet long; grow fast and is very long-lived feeds on herbs, fat earth worms, and aquatic insects, and any soft substance is extremely fertile and the prey of larger fish, aquatic birds, and frogs. body above blue-green the upper part of the sides greenish yellow and blackish, beneath whitish tall yellow scales large, longitudinally striated; of the gill is made a green paint, and of the sounds or air bladder a fish-glue.

7574. In raising carp, it is often the practice to have three ponds. — One for the purpose of spawning the fish in and in which they should be left during the rest of the summer and the following winter, as they mostly spawn from the beginning of May to the latter end of July another for the confinement of nursing up the young fry into which they should be put about the latter end of March or the beginning of April choosing a calm but not sunny day for the business, after which they should be carefully prevented from coming to the sides and being destroyed in this pond they may remain two years, and become four, five, or six inches in length, and good for use. The third or main pond is destined for the reception of the grown fish as those that measure a foot or more, including the heads and tails. The proportions in which these different ponds are advised to be stocked are these — For each acre of the first sort, "three or four male carps, and six or eight female ones;" the most suitable sort for this use being "those of five, six or seven years old in good health with full scale fine full eyes, and a long body without any blemish or wound. The ponds should be previously cleared of all sorts of venomous fishes and other animals, as perch, pike, eel, and trout; the water beetle, and also the newts or lizards." Such ponds as are warm and have an open exposure, with soft water are the most proper for this use all kinds of water fowl being kept from them. For the nursing ponds, a thousand or twelve hundred may not be more than sufficient for an acre and for the main ponds, one to every square of fifteen feet is the proportion advised, as their growth depends greatly on the room and quantity of food that is allowed. The best seasons for performing the business in this case are those of the spring and autumn. Some advise, in these cases, the stocking with carp or tench in the proportion of three to a square perch. In first stocking large ponds or waters, as where they are to the extent of three or four acres, carp, in the proportion of three hundred to the acre, are recommended and where they do not extend to such size, not so great a portion. And in stocking, after two or three years, four hundred to the acre.

7575. The tench (*Cyprinus Tinca* L. b) inhabits almost every where in stagnant waters; grows quickly and reaches from four to eight pounds weight. Is very fertile and tenacious of life, and will live all the winter under the ice feeds on worms and water plants. Is very voracious, and may be easily caught body covered with a thick mucus, and small scales which adhere firmly to the skin; above dark-green, the sides above the line green beneath yellow belly white varies in its colours by age, sex or the waters it inhabits; flesh white, soft, and well tasted.

7576. In stocking with tench the number per acre may be more than of carp. In Berkshire, where there are many ponds for the preserving of fish, they usually stock with tench or carp in the proportion of one hundred to the acre, the fish remaining four years in them but in the management of Mr Harry Fetherstone, in Sussex, in a pond of twenty acres reduced to sixteen by the deposition of mud, the stock is generally in the proportion of twelve hundred carp and an equal number of tench or at the rate of seventy five brace to the acre. And in this proportion they are said to succeed well.

7577. The gudgeon (*Cyprinus Gubio* L. c) is a very inferior fish to the carp or tench, but being of easy culture and rapid increase, is kept in many places as food for pike and perch. It inhabits gentle streams and lakes of Northern Europe is tenacious of life and very fertile about eight inches long feeds on herbs, worms, insects, the fry of other fish and parts of carcases body narrow spotted, above livid, the sides above the line blue, beneath whitish yellow but it varies its colour by age the different waters it inhabits, and its food. flesh white, and very grateful.

7578. The perch (*Perca vivipara* L. d) is an excellent fish and though naturally found in streams in Europe and Siberia, yet will live in large ponds or lakes, provided the water be clear. It grows to two feet long, back and part of the sides deep green with five broad black bars which are sometimes dark green or blue, and very rarely wanting belly white, tinged with red swims with great swiftness and at a certain height in the water is tenacious of life but eagerly takes a bait, feeds on aquatic insects and smaller fish spawns in May and June, and is very prolific it has no real air-bladder and from its insipidness may be obtained a kind of glue; flesh very delicate.

7579. In stocking with perch, as they are great breeders, six hundred to the acre may be sufficient.

7580. The pike (*Esox Lucius* L. e) inhabits most lakes of Europe, Lapland, Northern Persia, and North America, and is found even in the Caspian Sea swims, and grows very rapidly one to eight feet long; is extremely voracious and long-lived, feeds on almost any thing which comes in its way, even its own tribe; spawns from February to April body above black, the sides clearness spotted with yellow beneath white dotted with black; rarely orange spotted with black or green; scales small, close, hard. The pike is best reared in deep ponds by itself in which some gudgeons may be put to breed.

As its food. It will thrive in waters partaking of the chalybeate quality in which few other fish would live.

7597. The *gulf fish* (*Cyprinus carpio* L.) is an inhabitant of the rivers of China and Japan, and is introduced almost every where on account of its voracious and voracity; the others vary greatly, but are generally and mostly of a most splendid golden hue; scales large. It is bred in small ponds in gardens near London and Paris for sale, as an ornamental inhabitant of crystal vases, or garden basins of water.

7598. The minnow (*Cyprinus Phoxinus* L.), the dace (*C. luteus* L.), and the roach (*C. rutilus* L.), are very small fish, which abound, the first in gravelly streams, and the others in still waters. Both are useful as affording food to other fish and may therefore be put into fish ponds. They are also very good to eat.

7599. Of the trout and salmon family there are several species, as the lake trout, gilt and red charr, which inhabit Alpine lakes in northern countries, and might probably be introduced with advantage into the lakes of Cumberland, Westmoreland, and the Highlands of Scotland. The red charr is caught in Kewick lake. The salmon and salmon-trout (*Salmo salar* and *S. Trutta*.) require salt water and a river and the fresh water trout (*S. fario*) requires too rapid a stream for art to imitate they succeed, however, to a certain extent, in very slow-running waters which are clear.

7600. The salmon is a very prolific fish, both male and female are frequently fit for propagation during the first year of their age. The roe of the female is found, on an average, to contain from 17,000 to 21,000 ova or eggs. During the months of August, September, and October, the reproductive organs, both of the male and female, mature and have more or less completely reached maturity, at which period instinct of propagation impels them eagerly to seek rivers, and to ascend nearly to their source, in order to find a place suitable for the deposition of their spawn. They no longer, as in the winter and spring months, roam over the coast and shores, and return backwards and forwards with the flowing and ebbing of the tide, but pursue the most direct route by the mid-channel up the rivers and make the greatest efforts to overcome every obstacle, either natural or artificial, that may impede their progress. The spawning is accomplished in the months of November, December, and January. When the parent fishes have reached the spawning ground, they proceed to the shallow water generally in the morning or at twilight in the evening, when they play round the ground two of them together. After a turn, they begin to make a furrow by working up the gravel with their noses rather against the stream as the salmon cannot work with his head down the stream, for the water then going into his gills the wrong way drowns him. When the furrow is made the male and female return to a little distance one to lay the roe, and the other to the other side of the furrow. They then throw themselves upon their sides, and come together and rubbing against each other both shed their spawn into the furrow at the same time. This process is not completed at once as the eggs of the roe must be excluded individually from eight to twelve days are required for completing the operation. When the process is over they betake themselves to the pools to recruit themselves. The spawn thus deposited is afterwards covered with loam gravel; and in this state the ova remain for weeks, or sometimes much longer, apparently inert, like seeds buried in the soil. In an early spring the fry come forth early and later when the spring is late.

Generally they begin to rise from the bed about the beginning of March and their first movement is generally completed by the middle of April. The appearance which they present is that of a thick beard of grain rushing up in vast numbers. The tail first comes up, and the young animals often leave the bed with a portion of the investing membrane of the ova about their heads. From experiments that were made upon the roe, it appears that they can only be hatched in fresh water for when a portion of the roe was put into salt water none of the ova ever came into life; and when a young fish that had been hatched in fresh water was put into salt water it showed symptoms of uneasiness, and died in a few hours. When the evolution from the ova is completed the young fry keep at first in the eddy pools, till they gain strength, and then prepare to go down the river remaining near its sides, and proceeding on their way till they meet the salt water, when they disappear. The descent begins in the month of March, continues through April and a part of May, and sometimes even till June. The reason why the fry thus descend by the margin of rivers, and the mid-channel in estuaries, is apparently according to Dr Fleming, because the margin of the river is the ebb water and consequently best suited to their young and weak state; but when they reach the estuary or tide-way then the margin of the water being the most disturbed, the fry avoid it, and betake themselves to the deepest part of the channel disappearing alike from observation and capture, and so go out to sea, the smaller fry, as the fry are called, return again to the coasts and rivers, having obtained a pound or a pound and a half of weight by the middle of June they weigh from two to three pounds, and are said to increase half a pound in weight every week. They are now known in Scotland by the name of grilse, and by the end of the fishing season they have obtained the size of seven or eight pounds. In the first five months of its existence, that is, from April to August, both inclusive, it may be stated that the salmon reaches, in favourable circumstances, eight pounds weight and afterwards increases, though more slowly, yet so as to have acquired the weight of thirty five pounds in thirty three months. After the process of spawning is completed in the river the parent fishes retire to the adjoining pools to recruit. In two or three weeks from that time, the male begins to seek his way down the river; the female remains longer about the spawning ground, sometimes till April or May. The fishes which have thus spawned are denominated kelts. In their progress to the sea, when they reach the estuary they pursue a course precisely similar to the fry not roaming about the banks like clean fish, but keeping in the mid channel. They are at this time comparatively weak and in thus betaking themselves to the deepest part of the channel, they are better able to resist the deranging effects of the flood-tide, and to take advantage of the ebb tide in accelerating their migration to the sea. It appears that some which descend as kelts in spring return again in autumn in breeding condition a recovery which is no less remarkable than the early growth of these animals. The sea seems to be the element in which the salmon feeds and grows. When caught in fresh water, not only is their condition comparatively poor but scarcely any thing is ever found in their stomachs. In estuaries and on coasts, on the other hand, they feed abundantly and their stomachs are often found full of sand-eels. (*Edin. New Phil. Jour. Jan.—April, 1838.*)

7601. The eel (*Muraena anguilla* L.) inhabits almost every where in fresh waters grows sometimes to the length of six feet, and weighs twenty pounds; in its appearance and habits something resembles the serpent; during the night quits its element, and wanders along meadows in search of snails and worms; bolls itself deep in the mud in winter and continues in a state of rest; is very impatient of cold, and sometimes of life. The flesh of such as frequent running water is very good, is viviparous, and has 116 vertebrae. One advantage of the eel is, that it will thrive in muddy ponds of very small size, where no other fish would live.

7602. On the subject of outbreeding fishes it may be observed, that the waters of some ponds are better adapted for smaller sorts of fish than others. Thus, those where the water is thick and white are more adapted for carp; while such as have a thicker appearance, and where there is a greater deposition of muddy matter are better suited to tench. Perch are capable of being raised in almost any sort of ponds. Eels succeed best where the ponds are not very large but where fed by a spring, and there is a large portion of rich sediment. Pike should never be kept in ponds with carp or tench but in separate breeding-ponds, where the supply of small fry are considerable and not wanted for stores. Carp, tench, and perch are the only fish principally cultivated with a view to profit, with a few eels occasionally. But perch and eels should not be admitted where the ponds are but thinly stocked, as they are great devourers of the young fish. Carp and tench surver best together where the extent of the ponds are pretty large; as, in other cases, the former from being a much more powerful fish beats and deprives the latter of his

pond. Carp seldom afford much profit in ponds of less extent than half an acre; but tench thrive well in those of almost every size, being often found good in ponds of only a few perches square. Carp, perch and eels succeed well together; and also tench and eels. Carp seems frequently injure themselves by breeding thus together, though it sometimes happens with the latter. It is not improbable, but that in small ponds it may be the best practice to keep the carp and tench separate. The produce of profit afforded by fish ponds has not yet, perhaps, been sufficiently attended to in different situations to afford correct conclusions; nor is it well ascertained what is the annual increase in weight in fish of different kinds, in different periods of their growth, and under different circumstances of soil and water. Lovelock (*Journal of Agriculture*) states, that in Berkshire a pond of three acres and a half, drawn after being stocked three years with stores of one year old, produced of carp 125 lb. weight, of tench 230 ditto together 455 lb. which sold for 30s. 10s. or nearly 1l. 5s. per acre per annum.

7587. The fishing of *castrated fish* is generally done with nets, and sometimes by emptying the pond of water. Whatever way is adopted, only those fit to be used are taken, and the rest returned to grow larger. No fish is taken, or fit to be used, for a month before and after the spawning season, which with most fresh water fish is in April, May or June. The Marquis de Chabannes proposes to catch fish, both in fresh and salt water, by immersing a burning lamp in an air box with mirrors, and round which he has traps into which the animals are to be entangled, while approaching the light and the multiplied images of their own species. For this contrivance he has taken out a patent. Salmon are sometimes caught by torch-light.

7588. The *castration of fish* has been successfully practised both in this and other countries, and both with the male and female. Castrated fish attain to a larger size, and are in season at any period of the year. The mode of performing the operation is described in Ross's *Cyclopaedia*, art. *Fish, Castration of*; and in the *Philosophical Transactions* vol. 48. part II. p. 106.

7589. Of the *amphibians* which are or may be cultivated for food or ornament, the principal are the frog and tortoise.

7590. The *esculent frog* (*Rana esculenta* L. fig. 957 a) though generally despised in this country is yet an excellent article to those who are accustomed to it; and there are few Englishmen who have not a friend of the genus of this animal in France or Italy, but what would wish to do so again. The body of this frog is green with three yellow lines the middle ones extending from the mouth to the anus, with the angles of the mouth distended in a globular form the male makes a continual croaking in an evening, especially before rain; when irritated will pursue and destroy a pike. It is rare in England but very common on the Continent, where it is in season for the table in June.

7591. The *tree frog* (*Rana arborea* L. fig. 957 b) is green above and whitish beneath with a yellow curved line on the side. In elegance and activity it is superior to every other European species. In summer it resides in the woods and haunts the trees in quest of insects which it approaches on its belly in the same manner as a cat to a mouse, and at length seizes with an elastic and instantaneous spring. It is particularly noisy on the approach of rain. In winter it takes up its abode in the bottom of the waters, remaining till the spring in a state of torpor. The noise of this frog is by many considered musical and it is often kept in houses in Germany both as a curiosity and as a weather guide. It certainly deserves introduction to this country. We brought one from Carlsruhe in 1838 which has remained in a glass jar covered with gauze at the top, living on flies, till the present day Nov. 2. 1840.

7592. There are two species of tortoise which might be cultivated the common, and the mud tortoise. The common tortoise (*Testudo graeca* L. fig. 958 a) weighs three pounds, and the length of its shell is about seven inches. It abounds in the countries surrounding the Mediterranean and particularly in Greece, where the inhabitants not only eat its flesh and eggs, but frequently swallow its warm blood. In September or October it conceals itself, remaining torpid till February, when it re-appears. In June it lays its eggs, in holes exposed to the full beams of the sun, by which they are matured. Tortoises attain most extraordinary longevity and one was ascertained to have lived in the gardens of Lambeth to the age of nearly one hundred and twenty years. It will answer the purpose of a barometer and uniformly indicates the fall of rain before night when it takes its food with great rapidity and walks with a sort of mincing and elastic step. It appears to dislike rain with extreme aversion, and is discomfited and driven back only by a few and scarcely perceptible drops.

7593. The *mud tortoise* (*Testudo*, fig. 958 b) is common both in Europe and Asia, and particularly in France, where it is much used for food. It is seven inches long, lays its eggs on the ground though an aquatic animal, walks stinkier than the land tortoise; and is often kept in gardens, to clear them from snails and various wingless insect. In fish ponds it is very destructive biting the fishes and, when they are exhausted by the loss of blood, dragging them to the bottom and devouring them. The tortoise may be fed on any vegetable refuse, milk, worms, offal, or almost any thing. Linnaeus says several days after the head is cut off. (*Shaw's Zoology*.)

they are in all things extremely slow, and in copulation frequently adhere together a month, and live several days after the head is cut off. (*Shaw's Zoology*.)

## CHAP. XI.

*Insects and Worms which are or may be subjected to Culture.*

7894. *The silkworm and the honey-bee* are the two most valuable insects in Europe. The first, from its great importance, has recently engaged the attention of the legislature, no less than of private individuals, who have embarked large sums in the attempts now making to introduce its culture in this country on a large scale.

7895. *The silkworm* is the larva or caterpillar of a moth (*Bombyx mori* L., fig. 959):

It is a native of China, and was introduced into Europe A D 160. When full grown the worm is nearly three inches long, of a yellowish grey colour, with a horn-like process on the last joint of the body.

7896. *In Italy and other silk countries* the eggs are carefully preserved in some place of cool and even temperature, where they remain until the new leaves of the white mulberry which is its natural food, are produced. The object is to hatch the eggs precisely at this time, that the new born worm may be fed on food suitable to its infant state. A grower of silk never hatches a whole stock of eggs at once, as a night's frost will frequently destroy the leaves. Lettuce answers well in this stage of the worm's existence, but if it is fed entirely upon this plant the silk is of a very inferior description, and is, indeed, perfectly useless. The pabulum of the white mulberry in fact, is superior in nutritious matter to that of all others. The leaves in the autumn succeeding to those stripped in the spring are commonly given to cattle and pigs, who fatten upon them exceedingly. There is an unfounded prejudice in many silk countries that the silk produced from the second leaf is inferior to the spring crop, and in France and Italy the vernal leaf only is used. In India the mulberry tree is grown in moist places like the case in England and produces from three to six crops annually the prejudice therefore of the Italian and French growers against the second crop is unfounded. The real fact seems to be, that the worms are more difficult to breed in autumn than in spring, from the great change of temperature against which the growers in general make no artificial provision. Another reason may probably be, that the silk is reeled with greater economy and advantage in the height of summer when the length of the days and the heat of the weather is then sufficient to dry the thread in this operation. The native reeler of these countries are entirely unaccustomed to use artificial methods for creating a regulated temperature in houses or manufactories.

7897. *The ventilation and cleanliness of the nursery or rearing apartments*, and the preservation of a regular heat within them are highly important to the health of the worm. These points are much neglected on the Continent, where the nurseries are usually situated in the midst of the mulberry plantations, exposed to the external air and seldom cleaned. It was satisfactorily ascertained by M. Guzman de Morvan a few years ago that a ruinous and unexpected mortality which then raged among the worms, arose chiefly from want of ventilation and cleanliness. It has likewise been proved, by experiments lately made on a sufficiently large scale in Devonshire, that less mortality prevails among the worms in England than either in France or Italy.

7898. *In about six weeks* the worm reaches its full size previously casting its skin four times, and abstaining from food for some time before each change at these periods the worms are very sickly and a great mortality generally takes place. When full grown and about to spin, they exhibit symptoms of restlessness and uneasiness; small twigs of hawthorn or of other slender trees, are set up in the boxes or shelves, upon these the worms climb, each fixing upon its own berth. As it sometimes happens that two worms spin together forming what is called a double cocoon, this must be carefully prevented by separating them such a cocoon not only being difficult to run off when reeled, but two silks are produced injurious to the use of the thread the double cocoons are therefore always wound off by themselves. In preparing its case or cocoon, the worm first forms a loose envelopment of silken fibres, and then proceeds to enclose itself in a ball or case of an oval form, and finally changes into the pupa or chrysalis and after being thus enclosed for about fifteen days, becomes a moth. This, however is always prevented when the animal is not kept for breeding, otherwise the hole formed by the moth in effecting its escape would destroy the continuity of the silk, and prevent its reeling. The chrysalides are killed by two processes, by baking in an oven, or by letting them into a tight chest enclosing the cocoons. The latter method is preferable, as the heat can be better regulated.

7899. *The cocoons*, after the chrysalis is killed, is either reeled off at once, or sold to others who make this a distinct trade. The silk, as formed by the animal, is so very fine, that if each cocoon was reeled separately it would be totally unfit for use; the ends of four are therefore joined and reeled together out of warm water which softening their natural gum, makes them stick together so as to form one strong smooth thread. When the filament of any single cocoon breaks, or is exhausted, its place is supplied by a new one, so that the united thread may be wound to any length; the single filaments of the newly added cocoons are simply joined by being laid on the thread to which they adhere by their gum. The old apparatus for reeling merely consists of a large metal basin of water under which is a fire to keep it hot, and a reel of a pear and oven rude construction some important improvements, however, have been recently made in this machine. In reeling it is desirable that a round thread of equal thickness and smoothness should be produced, hence the filaments of which it is composed are equal and as firmly united as possible. When the skein is quite dry it is taken off the reel, and a tie is made with refuse silk at its two ends; it is then doubled into a hank, and is ready for sale. In this state it arrives in England, and is called raw

silk; the principal part is afterwards sent to a mill to be thrown, that is, to be twisted singly, or to have two or more ends of it doubled and twisted together to form singles, trams, or suspensives, in order to fit it for the loom. There are, however, purposes for which a single twisted thread is applied. We have before stated that a single thread is generally composed of the filaments from four cocoons, and that of these threads compose the organette or first cord of the warp of *filatures*; each thread is first spun or twisted, and then the four are thrown together into one. The warp is then generally composed of four raw threads simply twisted together. The reason of drawing so fine a silk on the reel as that composed of four cocoons, is, that the filaments, or attendant at the heels, cannot perfectly see more cocoons in one set, so as to replace the mode when the cocoons are exhausted. If a thread of sixteen cocoons were to be reeled, the filaments could not ensure regularity. Sometimes also would have only eight or ten cocoons, and at the last moment possibly twenty; consequently a most uneven silk would thus be produced. To prevent this evil, four cocoons are only run at once, and combined as before described. The important invention of Mr. Hesthouse, which we shall hereafter notice, applies to the object of drawing off sixteen or more cocoons at once on the reel, so as to form a thread as even as that produced by four cocoons, and thus abridge the expense of the subsequent processes of throwing. We understand this invention is fully appreciated by the reeling thread, and by the manufacturers at home, and that it produces an extraordinary improvement in the quality of the silk and a great reduction in its price. Mr. H. has obtained patents in the silk countries no less than in England for this invention, which there is every reason to think will be generally adopted.

7600. *Culture of the silkworm in England.* It is well known to those who have considered the subject, that the silkworm will breed and thrive very well in England, where the range and extension of temperature are within narrower limits than in France or Italy. The white mulberry flourishes equally well with us as in those countries. It remains, however, to be proved whether the weight of leaves produced on a given space of ground is equal to the average crop in warmer climates. This is evidently an important consideration in the question, of whether England can compete with foreign countries in the production of raw silk. The high value of land in a country so densely peopled as England, and the fact that the mulberry tree does not grow with great vigour, but also a clear ground immensely renders the prospect of profit from this branch of agriculture very questionable. A joint stock company, in the management of which all the cabinet ministers were more or less concerned was established in 1845, by the name of "The British, Irish and Colonial Silk Company." They possessed a very large capital and had formed extensive plantations of trees in several parts of England and Ireland, particularly near Windsor and Cork. Mr. John Hesthouse of Triverton, in Devonshire, has also applied himself to the investigation of this important subject with great assiduity, and, previously to the formation of the company above alluded to, had made considerable progress in the cultivation of the tree and the management of the worm. With the true liberality of a man of science, he presented to the company several thousand Italian plants destined for his own plantations, that they might commence their establishments without delay. It ought to be generally known, that to this gentleman we are indebted for the cheap production of that beautiful article called bobbin-net lace, which has become so important a branch of manufacture in England. It was as the attempt to render silk sufficiently even for his use in lace, that he made the discovery in reeling which we have before mentioned, and it is from the result of his investigations that the attention of government has so lately been directed to the subject. Admitting, as we have done, that no natural impediments exist against the successful culture of silk in England it will naturally be asked why all attempts hitherto made have been unsuccessful? This question embraces a variety of considerations, into which our limits will not permit us to enter at large. We may however observe that neither the mulberry tree nor the silkworm are indigenous to Britain. Centuries elapsed before even the south of Europe began their culture, which, commencing in the east of Asia, was propagated slowly and at distant periods westward. It obtained firm root in France during the reign of Henry IV. after great resistance on the part of the people whose prejudices against the application of land to this purpose excited frequent rebellions. The unsuccessful attempt of James I. to establish it in England is not accounted for; but the times which succeeded were unfavourable to the introduction of new arts and inventions. The manufacture of silk goods was introduced into this country in the fifteenth century and received a great stimulus by the revocation of the edict of Nantes in 1685. By this intolerant and disgraceful measure Louis XIV. drove thousands of his most industrious subjects to seek an asylum in foreign countries of whom it is supposed not less than 50,000 emigrated to England. From this period the manufacture of silk goods became an important branch of trade in England. The common and even still existing prejudice, that our climate is unfitted for the growth of the tree, and the production of the worm, would probably be still more inveterate in former times. The acknowledged fact that England is much colder than the south of France or Italy would naturally induce the idea that it was unsuitable both to the tree and the worms. Individuals among our countrymen have, however, constantly asserted the contrary and numerous unaided experiments have been brought forward in support of their opinion. Miss Croft of York, in 1792, sent to the Society of Arts a specimen of silk produced by worms fed entirely upon lettuce leaves. We are not told however whether proper trials were made by subsequent experiments to prove its quality, and we have already observed that such silk, for purposes of manufacture is perfectly useless, even in Italy. Yet we know it to be the opinion of men now perfectly conversant with the subject, that the various experiments and trials that have been hitherto made would long ago have succeeded, had we been fully informed on all the requisite points connected with the management of the tree, the worm, and its produce the cocoon. Our experimenters have all laboured under one difficulty—they were ignorant of the reeling process; and this probably arose from their experiments having been conducted on too small a scale to render it necessary to import or require the skill of reeling the silk from the cocoon. This difficulty has at length been overcome by the exertions of Mr. Hesthouse, at whose establishment in Devonshire the improved method of reeling is now carried on with complete success.

7601. *The recent attempt to establish the culture of the silkworm in Britain* appears to have completely failed for the present. After collecting a great quantity of mulberry trees, and establishing considerable plantations in Devonshire and near Windsor in England, and in the vicinity of Cork in Ireland, the company in 1838 gave up the whole, without, in our opinion, having given the attempt a fair trial. As the mulberry will produce abundance of leaves as far north as Stockholm, and as the worms have to be hatched and brought forth in artificial heat even in France, there cannot be a doubt as to the success of this branch of culture in any part of the British islands. Whether it would pay is a different thing; we by no means think it would, even in Ireland.

7602. *This common honey bee* (*Apis mellifica* L.) inhabits Europe in hollow trees, but is chiefly kept in hives, being domesticated every where. Perhaps more has been written on the economy of this insect than on any other animal employed in agriculture, and certainly to very little purpose. After all that has been done in England, France, and Italy, the bee is still more successfully cultivated and finer honey produced, in Poland, by persons who never saw a book on the subject, or heard of the mode of depriving bees of their honey without taking their lives. Much as has been written in France and England on this last part of the subject, it is still found the best mode to destroy the hive in taking the honey. Unanswerable reasons for this practice are given by La Grenade, a French apiculturist, which are elsewhere quoted by us at length (*Encyc. of Gard. vet. Bee.*), and

allowed to be so productive as to profit even by Husk. The honey produced by any hive or colony depends much more on the season, and the quantity and kind of flowers which the neighbourhood abounds, than on the form of the hive or artificial management. Viewing the subject in this light, we shall avoid noticing the mode of operating with glass, stinging, collaring, or other curious hives of recent invention, and treat only of the simplest methods. The author we shall follow is Howison.

7938. The entry, or place where the bee-hive are placed, should in very warm climates be made to face the east, and in order to direct the south east. It should be well protected from high winds, which not only prevent the bees from leaving the hive in quest of honey, but they also surprise them in the field, and often kill them by driving them against the trees and rocks or into rivers. The hives in an airy place should always be placed in a right line, but should the number of the hives be great, and the situation not spacious enough to admit of their being placed longitudinally it is more advisable to place them over one another on shelves (fig. 597) than in double rows on the ground. A bee, on leaving the hive, generally forms an angle of about forty five with the horizon. The elevation of the hive should therefore be about two feet from the ground in order to protect it from humidity. The greater the elevation of the hive, the longer is the flight of the swarms, and when they are at a certain point of elevation, the swarms are lost for ever to the proprietor. If the hives are to be placed in a double row, the hives on the shelves should alternate with those on the ground, the front ones, that when the bees take their flight no obstruction is offered to their ascent. Howison recommends placing every five upon a single pedestal, and at two or three feet distance from each other. By this means, when any thing happens to one hive, the others are less likely to be disturbed than when placed on a shelf in a bee-house; and the hives may be drawn down and locked. (fig. 598.) It is usual to have three or four legs or supports to the bee-boards, but those who have tried one will never resort to more, as one is a much better protection from vermin and insects. The space in front of the apiary should be kept clear of high plants for two or three yards.

7939. The variety of bees employed is a matter of some consequence. To the common observer all working bees, as to external appearance, are nearly the same, but to those who examine them with attention, the difference in size is very distinguishable, and they are, in their vicious and gentle, indolent and active natures, essentially different. Of the stock which Howison had in 1810, it required 250 to weigh an ounce, but they were so vicious and lazy that he changed it for a smaller variety which possesses much better dispositions, and of which it requires 500, on an average, to weigh an ounce. Whether size and disposition are invariably connected, he has not yet had sufficient experience to determine.

7940. The best material and form for hives is a straw thimble or flower pot placed in an inverted position. Hives made of straw, as now in use, have a great advantage over those made of wood and other materials, from the effectual defence they afford against the extremes of heat in summer and cold in winter.

7941. The size of hives should correspond as nearly as possible with that of the swarms. This has not had that attention paid to it which the subject demands, as much of the success in the management of the bees depends on that circumstance. From this instruction endeavour to fill with combs whatever hives they are put into, before they begin to gather honey. Owing to this, when the hive is too large for its inhabitants, the time for collecting their winter store is spent in unprofitable labour, and starvation is the consequence. The evil also extends to overseasoning late swarming the next summer, it being long before the hive becomes so filled with young bees as to produce a necessity for emigration, from which cause the season is too far advanced for the young colonies to prepare a winter stock. A full-sized straw hive will hold three pounds, a small-sized from one and a half to two pounds.

7942. The Polish Hive (Panczka Pol., fig. 591.) appears to us to be the second in merits to that described, and perhaps it may deserve the preference, if the mode of using it were generally known. It is simply the trunk of a tree, of a foot or fourteen inches in diameter and about nine feet long. It is scooped out (boring in this country would be better) for about six feet from one end, so as to form a hollow cylinder of that length, and of six or eight inches diameter within. Part of the circumference of this cylinder is cut out during the greater part of its length, about four inches wide, and a slip of wood is made to fit the opening. On the sides of this slip or segment (a) notches are made every two or three inches, of sufficient size to allow a single bee to pass. This slip may be furnished with hinges, and with a lock and key, but in Poland it is merely fastened in by a wedge. All that is wanting to complete the hive is a cover at top to throw off the rain and then it requires only to be placed upright like a strong post in the garden so as the bottom of the hollow cylinder may be not near the ground than two feet, and the opening slip look to the south. When a swarm is to be put in, the tree, with the door or slip opened, is placed obliquely over it, when the bees enter the door is closed and the holes stopped with clay till the hive is planted or placed upright. When honey is wanted, the door is opened during the finest part of a warm day when most of the bees are out, its entire state is seen from top to bottom, and the operator with a segar in his mouth, or with a lighted rag, to keep off the bees from his hands, cuts out with a crooked knife as much comb as he thinks fit. In this way fresh honey is obtained during the summer the bees are never cramped for room, nor does it become necessary to kill them. The old comb, however, is usually cut out, to prevent or lessen the tendency to swarming, which notwithstanding this and the size of their dwelling they generally do once a year, for the laws of nature are not to be changed. Though it be a fact that a small swarm of bees will not do well in a large hive, yet, if the hive extend in length and not in breadth it is admitted both by Huber and Hanks that they will thrive in it. "If too great a diameter," says Huber "be the hollow inner, their natural domestic, incontestably proves the truth of the assertion."

7943. The feeding of bees is generally deferred till winter or spring, but this is a most erroneous practice. Hives should be examined in the course of the month of September, or about the time of killing the droses; and if a large hive does not weigh thirty pounds, it will be necessary to allow it half a pound of honey, or the same quantity of soft sugar made into syrup, for every pound that is deficient of that weight; and in like proportion to smaller hives. This work must not be delayed, that time may be given for the bees to make the deposit in their empty cells before they are rendered torpid by the cold. Sugar simply dissolved in water (which is a common practice) and sugar boiled with water into a syrup, form exceedingly very differently suited for the winter stores of bees. When the sugar is wanted for their immediate nourishment, as in spring, it will answer equally as a syrup, but if to be laid up as stores the heat of the hive quickly evaporating the water, leaves the sugar in dry crystals, not to be acted upon by the trunks

of the bees. Bees may be killed with hunger while some pounds' weight of sugar remains in the hive in their cells. The holding of sugar into syrup forms a closer combination with the water, by which it is prevented from flying off, and a consistency resembling that of honey retained. Therefore, bees had frequent experience of honey, not containing a portion of honey preserved in perfect health through the winter with sugar so prepared, when given in proper time and in sufficient quantity.

760. To protect hives from the cold, they are covered with straw or rushes, about the end of September or later, according to the climate and season. This is an essential business, as well covered hives always prosper better the following season than such as have not been covered. In October, the aperture at which the bees enter should generally be narrowed, so as only one bee may pass at a time. Indeed, as a very small portion of air is necessary for bees in their torpid state, it were better during severe frosts, to be entirely shut up, as numbers of them are often lost from being exposed to quit the hive by the stimulus of a winter day. It will, however, be proper at times to remove, by a crooked wire, or similar instrument, the dead bees and other filth, which the living at this season are unable to perform of themselves. To hives, whose stock of honey was sufficient for their maintenance, or those to which a proper quantity of sugar had been given for that purpose, no further attention will be necessary until the breeding season arrives. This in warm situations, generally takes place about the beginning of May and in cold, about a month after. The young bees, for a short time previous to their leaving their cells, and sometimes, require being fed with the same regularity that young birds are by their parents. And if the store in the hive be exhausted and the weather such as not to admit of the working bees going abroad to collect food in sufficient quantity for themselves and their brood, the powerful principle of affection for their young compels them to part with what is not enough for their support, at the expense of their own lives. To prevent such accidents it is advisable, if during the breeding season it ran for two successive days, to feed all the bees indiscriminately, as it would be difficult to ascertain those only who require it.

761. The swarming of bees generally commences in June, in some seasons earlier, and in cold climates or seasons later. The first swarming is so long preceded by the appearance of drones, and hanging out of working bees, that if the time of their leaving the hive is not observed, it must be owing to want of care. The signs of the second are, however, more equivocal, the most certain being that of the queen, a day or two before swarming, at intervals of a few minutes, giving out a sound a good deal resembling that of a cricket. It frequently happens that the queen will leave the old hive, and return again several times, which is always owing to the queen not having dropped on the ground, or from having dropped on the ground, being too young to fly to a distance. Gooseberry, currant, or other low bushes should be planted at a short distance from the hives for the bees to swarm upon, otherwise they are apt to fly away by attending to this. Howson has not lost a swarm by straying for several years. When a hive yields more than two swarms, these should uniformly be joined to others that are weak, as from the lateness of the season, and deficiency in numbers, they will otherwise perish. This junction is easily formed by inverting at night the hive in which they are and placing over it the one you intend them to enter. They soon ascend, and apparently with no opposition from the former possessors. Should the weather for some days after swarming be unfavourable for the bees going out, they must be fed with care until it clears up, otherwise the young swarms will run a great risk of dying.

762. The honey may be taken from hives of the common construction by three modes, partial deprivation, total deprivation, and substitution.

763. Partial deprivation is performed about the beginning of September. Having ascertained the weight of the hive, and consequently the quantity of honeycomb which is to be extracted, begin the operation as soon as evening sets in by inverting the full hive and placing an empty one over it, particular care must be taken that the two hives are of the same diameter, for if they differ in their dimensions it will not be possible to effect the driving of the bees. The hives being placed on each other a sheet or large table-cloth must be tied round them at their point of junction, in order to prevent the bees from molesting the operator. The hives being thus arranged, beat the sides gently with a stick or the hand, but particular caution must be used to beat it on those parts to which the combs are attached and which will be found parallel with the entrance of the hive. The ascent of the bees into the upper hive will be known by a loud humming noise, indicative of the pleasure in finding an asylum from their enemy in a few minutes the whole community will have ascended, and the hive with the bees in it may be placed upon the pedestal from which the full hive was removed. The hive from which the bees have been driven must then be taken into the house, and the operation of cutting out the honeycomb commenced. Having extracted the requisite quantity of comb, this opportunity must be embraced of inspecting the hive, and of cleaning it from any noxious matter. In cutting the combs, however, particular attention should be paid not to cut into two or three combs at once, but having commenced the cutting of one, to pursue it to the top of the hive, and this caution is necessary for two reasons. If you begin the cutting of two or three combs at one time, were you to extract the whole of them, you would perhaps take too much, and secondly to stop in the middle of a comb would be attended with very pernicious consequences, as the honey would drop from the cells which have been cut in two, and then the bees, on being returned to their native hive, might be drowned in their own sweets. The bees also, in their return to their natural domicile, being still under the impression of fear, would not give so much attention to the honey which flows from the divided cells, and as it would fall on the board and from that on the ground, the bees belonging to the other hive would immediately scent the wasted treasure, and a general attack on the deprived hive might be dreaded. The deprivation of the honeycomb being effected, the hive may be returned to its former position, and reversing the hive which contains the bees, and placing the deprived hive over it, they may be left in that situation till the morning, when the bees will be found to have taken possession of their native hive, and, if the season proves fine, may replenish what they have lost. (Hives & Treatise on Bees.)

764. Total deprivation is effected in the same manner, but earlier in the season, immediately after the first swarm, and the bees, instead of being returned to a remnant of honey in their old hive, remain in the new empty one, which they will sometimes, though rarely, fill with comb. By this mode, it is to be observed, very little honey is obtained, the bees in June and July being occupied chiefly in breeding, and one, if not two, swarms are lost.

765. Supplication is performed when the season of flowers begins to decline, and generally in October. The smoke of paper or linen rag soaked or smeared with melted sulphur is introduced to the hive by placing it in a hole in the ground, where a few shreds of these articles are undergoing a smothering combustion; or the full hive may be placed on an empty one, inverted as in partial deprivation, and the sulphurous smoke introduced by a funneling bellows, &c. The bees will fall from the upper to the lower hive in a few minutes, when they may be removed and buried, to prevent resurrection. Such a death seems one of the earliest both to the insects themselves, and to human feelings. Indeed, the more deprivation of life to animals, not coloured with sentiment or reflection, is reduced to the precise pain of the moment, without reference to the past or the future, and at each pulsation of this pain increases in effect on the one hand, so, on the other, the susceptibility of feeling it diminishes. Civilised man is the only animal to whom death has terrors, and hence the origin of that false humanity, which condemns the killing of bees in order to obtain their honey, but which might, with as much justice, be applied to the destruction of almost any other animal used in domestic economy, as birds, game, fish, cattle, &c.

766. On the produce and profits of bees much has been said by the patriotic agriculturist. Bees, however, are extremely uncertain, and as to the profit, it can never be great, while there is the competition of all Europe in contact with us to honey and wax, and so great demand for swarms. Bees, however, are interesting creatures, and supported at almost no expense, and a hive or two is therefore very desirable in the garden of every farmer and cottager.

7616. *The common cray fish (Cancer Astacus L., fig. 952.),* called sometimes the fresh water lobster, inhabits still rivers, and forms holes in the banks.

7617. *They are said to be nutritious and of an excellent flavour and are prepared in cooking like lobsters or shrimps. In former times they were celebrated for many medicinal virtues, but these seem to be now forgotten. The flavour of these animals, nevertheless, depends entirely on the nature of their food. Like all others of their tribe, they feed principally upon flesh. They might be advantageously cultivated in ponds and marshes, but should not be put into fish ponds, as they are detrimental to the fry. A breeding stock may frequently be purchased in Covent Garden market, or procured from any of the small rivers near London; they are also said to be plentiful near Alnwick in Northumberland.*

7618. *The edible snail (Helix pomatia L., fig. 71 s),* although a native of the Continent, has been long naturalised in some parts of England.

7619. *It is the largest species found in Europe. The animal being fleshy, and not of an unpleasant flavour has been used as food from early times. It owes its introduction into England to certain medicinal virtues, no less than to its reputation on the Continent as an article of food. But the first of these properties has long since been forgotten, and no progress has yet been made in introducing it on our tables. It is not so abundant in Italy as the common garden snail (H. hortensis L.), which may be seen, exposed in cages, in the markets of Genoa and other cities. We have no certain information which of these species was held in repute among the Romans, who had their conchidia or stews, where snails were bred, and dressed with bean and added less of wine. The H. pomatia is preserved near Vienna in large pits, covered with boards, and fed with cabbage leaves and other vegetables.*

690. *The medicinal leech (Hirudo medicinalis L.)* grows to the length of two or three inches. The body is of a blackish-brown colour, marked on the back with six yellow spots, and edged with a yellow line on each side. But both the spots and the lines grow faint, and almost disappear at some seasons. The head is smaller than the tail, which fixes itself very firmly on any thing the creature pleases. It is viviparous, and produces but one young at a time, which is in the month of July. It is an inhabitant of clear running water, but in winter the leech resorts to deep water and in severe weather retires to a great depth in the ground, leaving a small aperture to its subterranean habitation. It begins to make its appearance in March or April. Water alone is not the natural element of leeches, as it is supposed, but conjointly with ground or mud.

7621. *The usual food of the medicinal and trout leech is derived from the suction of the jaws of fish; and leeches will not infrequently be found adhering to the fish themselves. But frogs form the most considerable portion of their food. Hence, the best leeches are found in waters much inhabited by these animals. The medicinal and trout leech do not, like the horse leech, take any solid food, nor have they the like propensity to destroy their own or any other species of the genus; but these the horse-leech will not hesitate to devour (Newton's Journal, vol. iv. p. 513.) If put into shallow clear ponds it will breed freely, and this is practised by some herballists and apothecaries in the neighbourhood of London.*

7622. *The use of leeches for the purpose of local bleeding is very considerable. There are four principal importers of leeches in London alone, whose average imports are said to be 120,000 per month each making a total of 480,000, or seven hundred two hundred thousand in one year. On the Continent, where they are obtained at a much cheaper rate, the numbers employed are enormous (Ibid.). The London market is partly supplied from the lakes of Cumberland, where the leeches are caught by women who go into the water bare-legged, and after a few have fastened, they walk out and pick them off. A good many are also brought from Holland.*

## CHAP. XII.

### Animals noxious to Agriculture.

7623. *Almost every animal may be injurious to the agriculturist in some way or other. All the cultivated live stock will, if not excluded by fences, or prevented by herding, eat or tread down corn crops or other plants in culture. Those animals, as the dog and ferret, which assist him in deterring or in catching noxious animals which would prey on others, will themselves become depredators if not attended to. And even man, the only rational, and therefore the most valuable of agricultural servants, will prove, under certain circumstances, the greatest of all enemies to the agriculturist. We shall glance at the different animals more especially noxious in the order of their usual classification.*

#### SECT. I. Noxious Mammalia.

7624. *Of noxious Mammalia man, in a demoralised state, is the most injurious. The remedy is furnished by the law;—the preventive is good education, and civil and kind treatment by the master.*

7625. *The fox (Canis Vulpes) commits great ravages among lambs, poultry, geese, &c. To destroy it, the farmer must take a sheep's pounce and fasten it to a long stick; then rub his shoes well upon the pounce, that the fox may not scent his foot. He should then draw his pounce after him as a trail, a mile*

or upwards, till he gets near some large tree; then leave the panache and ascend into the tree with a gun; and as the night comes on, he may see the fox come after the scent of the trail, when he may shoot him. The trail should be drawn to the windward of the tree, if he can conveniently contrive so to do. — Or, set a steel-trap in the side part of a large field, distant from paths and hedges; then open the trap, place it on the ground, cut out the steel-spring thereof in a turf, and take out just so much earth to make room for it to stand, and then cover it again very neatly with the turf you cut out. As the joint of the turf will not close exactly, procure some mould of a mole-hill newly thrown up, and stick some grass on it, as if it grew there. Scatter some mould of the mole-hill very thin three different ways, at the distance of ten or twelve yards from the trap, let this mould be thrown on spots fifteen or sixteen inches square; and where the trap is placed, lay three or four small pieces of cheese and then, with a sheep's paunch, draw a trail a mile or two long to each of these three places, and from thence to the trap, first the fox may approach one of the places first for then he will advance to the trap more boldly; and then you will be almost always sure of catching him. You must take care that your trap be left loose, that he may draw it to some hedge or covert, or he will otherwise bite off his leg and so make his escape. — Or near the spot where the fox uses much to resort, fix a stick or pole, much in the same manner as for a woodcock. To explain this more exactly: tie a string to some pole set fast in the ground, and to this string fasten a small short stick, made thin on the upper side, with a notch at the lower end of it: then set another stick fast in the ground, with a nick under it: bend down the pole, and let the nick or notches join in the slightest degree, then open the noose or string, and place it in the path or walk of the fox. By throwing fresh-meat, pieces of cheese, &c. as you pass along you may entice the fox to take the same road.

7630 To shoot a fox, ascend the sides of the shoes with seven a set, a little broad: then go towards the wood, and, in returning, drop here and there a bit of some's liver, roasted and dipped in honey, dawning after you a dead cat: and by these means he will be allured to follow you.

7631 The fox is sometimes taken with a hook made of large wire, and curving on a swivel like the collar of a greyhound: it is usually hung so high from the ground that he is compelled to leap to catch at it, and baited with fresh liver cheese &c. and if a trail be run with a sheep's paunch, as before directed, he will be drawn to the bait with the greatest ease.

7632 The pole-cat (*Felis fulvens L.*) may be caught and destroyed by a dead-fall, constructed in the following manner: — Take a square piece of wood, weighing forty or fifty pounds: bore a hole in the middle of the upper side, and set a crooked hook fast in it: then set four forked stakes fast in the ground, and lay two sticks across, on which sticks lay a long staff, to hold the dead-fall up to the crook, and under this crook put a short stick, and fasten a line to it: this line must reach down to the bridge below, and thus bridge you must make about five or six inches broad. On both sides of this dead-fall place boards or rails, or edge it with close rails, and make it ten or twelve inches high. Let the entrance be no wider than the breadth of the dead-fall. — A pigeon house, surrounded with a wet ditch, will tend to preserve the pigeons: for birds of prey naturally avoid water.

7633 The weasel or *Mustel* (*Felis vulgaria L.*), though in some respects beneficial, as so much as when domesticated it destroys rats, mice, moles, and other noxious vermin is nevertheless, in a wild state, a formidable foe to poultry and rabbits. Weasels may be destroyed by putting in their lair small pieces of paste, consisting of pulverised sal ammoniac, mixed up with the white of an egg, wheaten flour, and honey. The strewing of rue round the place where hens nestle, is also said to drive away these depredators: as also will the smell of a burnt cat: as all animals are terrified at the burning of one of their own, or of a similar species.

7634 The badger (*Urocyon ferox L.*) destroys great numbers of young pigs, lambs, and poultry every year. Some use a steel-trap, or a spring, such as foxes are taken in, to catch them. Others sink a pit-fall, five feet in depth and four in length, forming it narrow at top and bottom, and wider in the middle: they then cover it with small sticks and leaves, so that the badger may fall in when he comes on it. Foxes are sometimes taken in this manner. Others, again, pursue a badger to his hole, and dig him out: this is done by moonlight.

7635 The mole (*Tupa europæa*) is insidious by the subterraneous roads and hills of earth which it forms in grass lands. With regard to the removal of mole-hills various practices are in use: but the most effectual is that derived from the experience of a successful mole-catcher and communicated to the public by Dr. Darwin, in his *Zoölogia*. This man commenced his operations before sun-rising, when he carefully watched their situation and frequently observing the motion of the earth above their walks, he struck a spade into the ground behind them, cut off their retreat, and then dug them up. As moles usually place their nests at a greater depth in the ground than their common behaviour led, and thus form an elevation or mole-hill, the next step is to destroy these nests by the spade: after which the frequented paths are to be distinguished from the bye-roads, for the purpose of setting subterraneous traps. This object may be effected by marking every new mole-hill with a slight pressure of the foot, and observing the next day whether a mole has passed over it, and destroyed such mark: and this operation should be repeated two or three mornings successively but without making the pressure so deep as to alarm the animal, and occasion another passage to be opened. Now, the traps are to be set in frequented paths, and should be made of a hollow wooden semi-cylinder (*fig. 262.*) each end of which should be furnished with grooved rings, containing two nooses of horse-hair that are loosely fastened to the centre by means of a peg, and are stretched above the surface of the ground by a bent stick or strong hoop. As soon as the mole passes half way through one of these nooses, and removes the central peg in its course, the hoop, or bent stick, rises in consequence of its elasticity and of course strangles the mole. The simplicity of this mode of destroying mole-hills and moles recommends itself to general adoption: as those whose grounds are thus infested may easily extirpate them by teaching this practice to their labourers.

7636 The *Domestic Norway rat* (*Mus Rattus L.* *fig. 263.*) is now generally diffused throughout this country where it has almost extirpated the indigenous black rat. It is the most noxious quadruped we have, as it is destructive both to the live and dead stock of the farmer. The following methods for destroying it are preferable to all others, and are given in *Willen's Domestic Economy* vol. ii. — Fry a piece of sponge with salt butter in a pan then compress it between two plates, and cut it into small pieces, and scatter them about the holes frequented by rats and mice. This preparation is covered with uric acid, it excites thirst in the animals, which should be gratified by exposing shallow vessels containing water. On drinking this fluid, after having swallowed the burnt sponge it distends their stomach, and proves a fatal repast. — Or a capacious cask of moderate height must be procured and put in the vicinity of places infested with rats. During the first week this vessel is only exposed to allure the rats to which no other part of the cask by means of boards or planks arranged in a sloping direction to the bottom, which are every day strewed with oatmeal, or any other food equally grateful to their palate, and the principal part of which is exposed on the surface. After having thus been lulled into security, and accustomed to find a regular supply for their meals, a skin of parchment is substituted for the wooden top of the cask: and the former is cut for several inches, with transverse incisions through the centre, so as to yield on the smallest pressure. At the same time, a few gallons of water, in the depth of five or six inches, are poured into the empty cask. In the middle of this element a brick or stone is placed, so as to prevent one or two inches above the fluid, and that one rat may find on the former a place of refuge. These preparatory measures being taken, the boards as well as the top of the cask should now be furnished with proper bait, in order to induce them to repeat their visit. No sooner does one of these misadventured plungers

263

through the angles of the parchment into the vessel, than it retreats to the brink or vice, and commences its lamentations for relief. Now are the plaining notes uttered in vain. Others soon follow, and show the same fate, when a dreadful conflict begins among them, to decide the possession of the dry asylum. Besides these in rapid succession, attended with such loud and noisy shrieks, that all the rats in the neighbourhood listen to the final exit, whence they experience similar distress. Thus hundreds may be caught by a vineyard, which might be greatly facilitated by exposing a living rat taken in a trap, or purchased from a professional rat-catcher.

7651. A powerful mode of catching rats has been lately practiced by Broad, a Farmer at Thrumton in Herefordshire. He uses a box trap, two feet long, eight inches wide, and nine inches deep, and little different in construction from the common one. His secret consists in scenting light-coloured malt, and also some wheat straw, with oil of caraway, and not setting the traps for a day or two till the rats have been accustomed to eat the malt without fear. (*J. Mag. civ. p. 451.*)

7652. *Food of Norway's rats* is thus described by H. Taylor Esq. in the *Gardener's Magazine* :—

7652. This ratery was invented by Mr. R. Paul of Stanton, in Herefordshire. He had found much labour and time in taking it to gardeners; and, though living in a situation peculiarly favourable for observing the food of rats, used to hear that he had completely vanquished them. In this, I have heard him say that he uttered a reward to any one who would bring him on the premises; and that having method and turned off one

yearling year, he hated a rat; that he should soon catch them both, which, in the course of a very few days, he did. He stated, as the site of his ratery, some distance where rats were known to frequent, and which he could lock up, and keep round to his own device and operations. Here he fixed his trap, the construction of which will be best understood by referring to the accompanying sketches (Figs. 504, 505). This

964

The same letters refer to each of the figures.

A. End view of the trap, with the tub (bottom).

B. Longitudinal section of trap.

C. End view of longitudinal section of trap.

a. Doubting Castle.

A. Partition Hoop.

c. Hoop of Despatch.

d. Partition wall.

e. Ground level.

f. Tip of bait or tin.

g. Falling floor or bottom of trap.

h. The weighted end of the fall, to bring it back into its place.

i. The end of the fall, that gives way under the rat.

k. Trough or threshold, in which the trap (a) is placed.

m. The sliding end of the trough.

n. The end at which the rats enter.

o. Loose wood, to serve both as a cover and a road into the trap.

p. A slip of wood, up which the rats spring from the plate d, and which gives way under them, and lets them feel the water below.

SECT. II. *Birds injurious to Agriculture.*

7633. *Of birds, the most decidedly injurious to man are the different hawks and kites, as most of the species attack and devour young poultry*

7634. *Various methods have been proposed for remedying this evil, but they evince little acquaintance with the habits of these birds.* Mr Swanson recommends that the prevalent custom, of sailing such as have been killed against barn-doors or out-houses, be exchanged for the following. — In such parts of the country as are frequented by these birds, let two or three poles, ten or twelve feet high, be placed in the farmer's poultry yard, each pole being furnished with an iron spike six or eight inches long, pass this spike through the body of a dead hawk in the direction of the back-bone. It will thus be firmly secured, and give the bird an erect position: the wings being free will be moved by every breeze, and their unusual position will prove the best scarecrow either for ravenous or granivorous birds, more particularly the latter. Destruction by the gun is of course the most effectual.

7641. *Whether granivorous birds are more injurious than beneficial to the farmer, is very questionable.*

7642. The crow, raven, raven, sparrow magpie and starling are commonly called granivorous: yet this is an error, for they are all omnivorous, that is, feeding both upon animal and vegetable substances, and more particularly upon insects. We are annually told of large crops being either wholly or partially destroyed by locusts of some sort or other; but we never hear that these injuries have been occasioned by birds. These complaints have certainly been more numerous of late years than formerly and this is attributed by Mr Swanson to the destruction of small birds (as waste lands are brought into cultivation); to the great diminution of reekeries; and to the foolish prejudice which the generality of farmers have taken up against these latter birds, which they destroy without mercy. In the instance we have been less wise than our ancestors, who protected and cultivated them, and by whom they were justly considered of the greatest benefit to mankind. Madame de Sévigné, indeed, to have printed this out to us, for she has distinguished the crow in all parts of the habitable world. Yet the farmer will enquire, "What good can these birds do me, when they come on my newly sown land, and root up the seed?" The answer is very short. The crows and rooks do not come for the express purpose of eating or destroying the seed: but for devouring the insects, snails, and grubs turned up by the plough or harrow; these are their favourite food, and while so occupied, the small quantity of seed they may eat or displace is returned to the farmer ten-fold by that saved from the insects. Walke, in speaking of the destruction caused by the hedgehogs or erichonids, says, that "whole meadows and corn-fields were destroyed by them: and judiciously concludes by observing, "that the many rooteries with us is the reason why we have so few of these destructive insects." (*Hist. of Northumberland*.)

SECT. III. *Insects injurious to Agriculture.*

7643. *Insects, above all other animals, are by far the most injurious to the agriculturist not only from their numbers, but from their attacking the produce of the earth in all its stages of growth and maturity.* We have already pointed out the advantage, not to say the necessity, of a certain knowledge being acquired respecting insects, by all persons engaged in agricultural pursuits. We shall now explain in popular language, the different tribes or orders into which they are divided: the changes they undergo; and the injuries they produce to man, and the animals and vegetables which he cultivates. Numerous insects, much more destructive than those we shall enumerate, are found in other climates, but from which the British agriculturist has, happily nothing to fear, and therefore need not be acquainted with. The reader will however, find much valuable information respecting them concentrated in Kirby and Spence's *Introduction to Entomology*, vol. 1.

SUMMARY. 1. *Physiology of Insects.*

7644. *Insects are distinguished from worms (Vermes I.) by always having feet in their perfect state, as the beetle, butterfly, &c.* Worms crawl upon their bellies and have no feet, as the earth-worm, slug, snail, &c. The generality of insects have only six feet: but some few generally called by this name, have a great many, as the wood-lice, centipede, &c.

7645. *Nearly all insects are oviparous* (that is, produced from an egg. These eggs are seldom found singly; they are small in size, and do not grow. The eggs of some species are hatched in a few days, while those of others remain during the winter and the young do not come forth until the season at which the larvae of the plants upon which they feed begin to expand.

7646. *The second state of the insect is called the larva, or larva in systematic language, and is known to the vulgar by various names.* Caterpillars are those larvæ which are exposed, and feed upon leaves and plants, as the caterpillar of the common cabbage butterfly (Ag 971. c). The larvæ of beetles usually live in the earth, in the trunks of trees, or in the substance upon which they feed; they are generally of a whitish colour, thick and clumsy in form and are called grubs. The larvæ of the common cockchafer (Ag 971. b) and of the nut-hatch (Ag 971. c), are of this description: while the name of maggot is usually given to the larvæ of flies, bees, wasps, &c., all of which live in the same confined state as those of beetles. It is in this stage of existence that insects are most voracious, and consequently most destructive to plants.

7647. *When the larva has attained to its full size it changes into the p. p. or chrysalis state.* This is done in different situations, according to the tribes to which they belong. The chrysalis of butterflies (Ag 971. b, c) are naked, and are either suspended or attached to trees, branches, walls, &c. Those of moths are either encased in a case like the cocoon of the silkworm, or the caterpillar undergoes its change in the earth. The period in which insects remain in this state varies according to the species: but in most cases they are inactive and torpid.

7648. *The third, or perfect stage, is produced from the chrysalis, and is the only state in which all its parts and members are fully developed.* The appearance and anatomy of perfect insects, in general, highly different from those of the larvæ and pupæ, and it is only in its final stage of existence that the species can be ascertained. With the exception of such insects as form the A. piers of Linnaeus, all others are furnished with wings, either four or two in number. Some few exceptions, however, occur to this rule; the female of the glow-worm and of some few moths are apterous, while many beetles (although furnished with hard winged cases) are destitute of real wings.

7666. The duration of *hæmetis* is extremely variable: the greatest proportion appear to be annual, emerging from the egg and passing through the three stages of their existence within the space of a year. But there are a great number of species, particularly among the beetles, which pass three, and even four years in the caterpillar state, and metamorphose on record of hatching consisting of fifteen years. The greatest proportion of insects are biennial, passing the winter in the chrysalis state, and closing their existence in the succeeding summer. The transitory life of the *Apodemus* is proverbial; the perfect insect indeed exists but for a day, and seems born only to continue its species; yet in the larva state it enjoys a life of one, two, or even three years.

### SUMMARY 2. Arrangement or Classification of Insects.

7650. All insects as Macleay observes, may be divided into two groups; 1. *Apterous insects* having either no metamorphosis, or only that kind of it the tendency of which is confined to the increase of the number of feet: these, as their name implies, are destitute of wings. 2. *True insects*, or those whose metamorphosis has a tendency to give wings to the perfect or imago state, but never more than six feet.

7651. True insects are again dividable into two primary groups; the first of these are organized for usefulness in their perfect state, and the second are organized for station alone. Each of these divisions according to the system of Macleay contains five separate orders, the principal characters of which we shall endeavour to make intelligible in common language.

7652. The *Mamodibula*, or *masticating insects* are furnished with jaws of a horny or membranaceous substance, infinitely diversified in their form and structure. They are divided into the following orders:—

1. *Triphlebotæ*. The wings are four, soft, and generally transparent; the upper pair slightly hairy, and the lower pair velvety at base. The insects of this order are comparatively few. The embryo or caterpillar, in the larva of the spring fly (*Phryganea*), and lives in the water, concealed within

a tube of its own construction. There are many species in this country, well known in their perfect state, in all levels of nature. *Phryganea tibialis* (fig. 967 c) may serve as an example of this order.

2. *Rhynchophora*. The wings are four, close and transparent. The tarsi (or outer division of the foot) is composed of five joints, and the body is armed with a sting. The bee, the ant, and the wasp, are familiar examples.

3. *Coleoptera*. This well defined and most extensive order comprehends all insects known by the name of beetles. They have two wings, concealed beneath a pair of hard wing-cases, which meet close together in a straight line down the back. There are many tribes of these insects, which, both in their larva and perfect state, are extensively injurious to man.

4. *Orthoptera*. The true wings are but two, very large when expanded, and folded lengthways when at rest. They are covered, either partially or wholly by two wing-cases of corn, tough, and rather opaque substance, somewhat resembling parchment, and reinforced with small veins. The leading characters of this order are exemplified in the *Blatta*, or cockroach.

7653. The *Hæmetis*, or *suctorial insects*, likewise contain five orders. Although apparently destitute of jaws, there is every reason to believe, from the observations of the celebrated Linnæus, that the rudiments of the masticating organs exist in these insects, but that they are so slightly developed as to be totally useless, and only discoverable under a very strong magnifier. The suctorial insects in their larva state are mostly furnished with strong and well defined jaws, and feed voraciously upon animal and vegetable bodies: yet, from the perfect insect being supported by suction alone, it is obvious that in this state they can do no injury to the agriculturist. The orders into which they have been divided are these:—

1. *Leptidoptera*. The wings are four, thin, membranaceous, and covered with a fine powdery substance, which, by the magnifying glass, is shown to consist of minute scales, lying one upon another, like those on fishes. The beauty and variety of these are familiar to every one as well known examples of these insects, the larva of which are called caterpillars. The *Papilio urticae*, or small purple-shell butterfly (fig. 968), will serve as a good example of the egg (a), larva (b), and pupa state (c) of most day flying lepidopterous insects.

2. *Exoptera*. The wings are two, clear and transparent, like those of the common house fly. This order is very numerous, and contains many insects which are injurious to vegetation as larvae, and troublesome to man in a variety of ways in this part (China), where they (Typhlocyba) cause the *typhlocyba*, &c.

3. *Homoptera*. The wings of the last century arranged all insects belonging to two orders. But it is now considered, by Linnaeus and Macleay, to each only as larvae. Twelve articulated joints render them capable of sucking, and no wings, as in the case of the common cicada.

4. *Mamodibula*. Insects of this order are furnished with two folded wings, covered by which are also covering over each other, of a thickened substance, and which are likewise used as organs of flight. The tarsi are composed of three, two, or sometimes only of one joint, and the body is much flattened. The various insects commonly called *delphids*, which need a strong and disagreeable smell when handled, are all arranged under this order.

5. *Neuroptera*. These insects have a great resemblance to the last; but the body instead of being depressed and flat, is

much the part of typical structure, and frequently troublesome in our kitchens and barbers.

3. *Neuroptera*. The wings, with very few exceptions, are four in number, clear, transparent, and reticulated with numerous veins, or irregularly square divisions: the tail of the female is not armed with stings. Few if any of these insects may be considered as perfect enemies to man, but, on the contrary, from their predatory habits, they attack and devour a vast number of smaller insects. This is more particularly the habit of the green dragon-fly (*A. viridis*), fig. 967 a, which every one may see, during summer, hovering over ponds, and flying about the hawks in search of its prey. The *Apodemus*, or day fly (*E. vulgaris*), fig. 967 b, likewise belongs to the order, and, although not very numerous in this country, is so abundant on the Continent, that they are collected annually in barrels, and offered to the apothecaries, whole and valuable manure.

ovoids and thick; the other also, instead of being filled over with others, are flattened, and contain the skin of the body. These are, consequently, the immature insects in question; but the *Chrysomelids* (*Chrysomelids* *g.*) is a good example when in its perfect or winged state. The larva resembles in a

drop of blood of its own redness, and is then commonly known as the *crimson-spotted insect*; depending upon the way it stains the leaves as well up and the growth of young plants in the same manner.

1066. The different orders of insects we have now enumerated are connected by others of an inferior extent, and which are called *coherent orders*. But as a description of these is not essential to our present purpose, and as they do not contain any decidedly injurious insects, we shall merely refer the reader to the *British Entomological* and the *Entomology* of Messrs. Kirby and Spence.

#### SECTION 3. Insects injurious to the Stock.

1067. All organized beings, whether animal or vegetable are subject to be attacked and destroyed by insects. Even man himself is not exempt from the dominion of these small but formidable creatures. For some uses but unknown purpose, there are peculiar species appropriated to receive their nourishment from man alone, and which cannot exist in any other situation. The remedies for these must be prescribed by the physician; but it is the business of the intelligent agriculturist to make himself acquainted with such as are injurious or hurtful to the animals and plants, upon which, the success of his operations mainly depends: for there are as yet no agricultural physicians, to whom the farmer can apply for advice or information when his labours are counteracted by insect devastators. We shall therefore briefly notice the domesticated animals and cultivated plants most subject to these injuries, pointing out the most efficient means by which they may be checked.

1068. The horse. The principal fear to this noble animal are the horse-fly (*Tabanus* *g.*) and gad-fly (*G. hirsuticornis*). The first deposits its eggs on such parts of the body as are liable to be licked by the tongue; and the animal, unconscious of what it is doing, thus conveys its enemy into its stomach: the young larvae are there nourished, and become whitish rough maggots (*fig. 968. c*) which are known by

the name of bots. They attain their full size about the latter end of May, and are voided by the anus from that time until the end of June. On dropping to the ground, they find out some convenient retreat, where they change into a chrysalis and in six or seven weeks the fly appears. The female (*a*) is distinguished from the male (*b*) by the lengthened shape of her body. The inside of the knee is chiefly selected for depositing her eggs, which are frequently amount to four or five hundred on one horse. The other species (*c*, *d*, *e*, *f*) is still more troublesome, it deposits its eggs upon the lips, and causes excessive and distressing uneasiness to the animal. Mr. Bracy Clark, who has investigated the history of these insects with great ability, observes that in ordinary cases it is not improbable that they are beneficial to our cattle, by acting as perpetual stimuli or blisters: yet, when they exceed certain limits, they produce disease, and sometimes death. (Clark in *Linn. Trans.* vol. iii.) The prevention of bots belongs to the farmer the more to the veterinary surgeon. The first may be effected by washing the animal at the season when the female deposits her eggs (usually in August and September) and should the horse appear much agitated in its pasture, there will be good reason to suspect it has been attacked by the fly: the eggs may then be removed by the brush and currycomb, or by a pair of scissors. When the disease is certain, one of the best methods to destroy the insect is to fasten a bag net on the horse, for the purpose of catching the excrement, as well as the full-fed larvae. By throwing the dung every morning into a deep pit, any larvae that may be enclosed in it will thus be prevented from working their way to the surface when their last transformation is about to take place, and their death will cut off a numerous progeny. There are other dipterous insects which feed upon the blood both of horses and cattle. The most formidable of these are the horse-flies (*Tabani*, *f*); others, much smaller (*Stomoxys calcitrans*) assail him in every situation during summer and dart their long proboscis into his legs and belly. But none are more trying to him than the sweat fly (*Hippoboscus equina* *L.*) which runs sideways or backwards like a crab, and settles itself in those parts least covered by hair: it may however, be caught by the hand when the animal is in his stall; but its substance is so hard, that it can only be destroyed by rolling it between the finger and thumb.

1069. Horned cattle are likewise subject to the attacks of a peculiar species of gad-fly (*G. bovis*, *g.*) which causes them great terror and distress. The larva (*a*) is smooth and fat and the chrysalis (*b*) opens by a lid (*c*) when the insect (*d*) emerges from it. The herdsman may know when this insect appears among his flocks, by the agitation they exhibit, the whole herd, with their tails erect, or carried in some grotesque attitude, gallop about and utter loud lowings. When oxen are employed in agriculture, the attack of this fly is often attended with danger as they become quite unmanageable, and, whether in harness or yoked to the plough will run directly forward. Their harness at this season should therefore be so constructed as to be easily loosened. The eggs are deposited within the skin of the animal, and in a wound made by a tube resembling an anther, with which the female is provided. These flies only attack young and healthy subjects; but, independently of the terror they create, do not appear to occasion any material injury. The cattle of Hungary and the neighbouring countries, as also those of Abyssinia, are subject to more deadly enemies, which herdsman are unknown in England.

1070. Sheep are also infested by another species of gad-fly (*G. ovis* *L.* *g.*, *h.*, *i.*), which deposits its eggs in the inner margin of their nostrils. The moment the fly touches this part of the sheep, they shake their heads, and strike the ground violently with their fore feet; at the same time, holding their noses close to the earth, they run away looking about them on every side to see if the fly pursues: they will sometimes creep together in a rut or dusty road with their noses close to the ground. The larvae (*j*) are white, fat on one side and curved on the other: they inhabit the nostrils of the nostrils sinuses, and crawl, when the animal is dead, into those of the horns and frontal sinuses; when full grown, they

fall through the month, and change to the chrysalis (h), which produces the fly (g) in about two months. Swine, pigeons, and all kinds of poultry are subject to them, and here of various kinds, but never to such a degree as to occasion death.

7050. Flies, in their young or fly state, are the food of the larvae of water beetles (Dytids). These insects are frequently seen in great numbers in ponds; they may be caught by a hand net (made of very small meshes), inserted beneath the insect, as he respires (with his head downwards) on the surface, and then suddenly drawn upwards.

#### SUMMARY. 4. Insects injurious to Vegetables.

7050. The ravages of insects upon plants commence from the time that the seed is committed to the ground, and continue until the produce is gathered into the barn. These various injuries, in one shape or other are annually experienced, and many of them, beyond all doubt, will hereafter increase to an alarming extent, if the great body of agriculturists persevere in their mistaken prejudices against crows, rooks, and other useful birds, which Providence has kindly given us, to keep the insect tribes within due limits. We have already noticed the destructive insects which are in a great degree peculiar to certain plants, as wheat, barley &c. in a general way (Part III. Book VI.) we shall now enumerate those that infect the grain, clover pastures, cabbages, and fruits, plantations, as well as those universal destroyers of all vegetables, the wire-worm, the plant louse, and the different species of crane-fly.

7051. Wheat, in every state, is subject to many insect depredations. Mr. Marshall describes a small grub (by some mistaken for the wire-worm), which eats into the young plant about an inch below its surface, devours the central part, and thus causes its immediate death. Out of fifty acres sown with wheat in 1805, ten had been destroyed in this way so early as October. At a later period this grub is attacked by a fly nearly related (according to Mr. Kirby) to the *Moschus aculeatus* of Latreille. It makes a lodgement in the heart of the principal stem just above the root, which stem it invariably destroys, giving the crop at first a most unpromising appearance; but it proved ultimately that the plant, instead of being injured derived great benefit from this circumstance for the main stem germinating, the root (which was not hurt) threw out fresh shoots on every side, so as to yield a more abundant crop than in other fields where the insect had not been. When first observed in England, this insect caused great alarm among agriculturists, who thought it might prove the Hessian fly. When the wheat blossoms, it becomes exposed to the attack of a small orange-coloured gnat, which deposits its eggs in the centre of the flower; the larva of grub devours the pollen, and thus prevents the impregnation of the grain. The weevil, a small coleopterous insect (*Callosa granaria* L.) is extremely destructive to wheat when in the granary where it feeds both in the larva and perfect state against the first, we are acquainted with no remedy as it lives in the grain but as this is larger than the perfect beetle, the latter may be in a great measure collected by means of a sieve, large enough for the insect (but not the grain) to pass through it is often found in such numbers, that they have been collected and destroyed by bushels. The same insect, or one very near it, often infests us, and can only be killed by baking or heating the biscuits over again in an oven.

7052. Rye is subject to the attacks of a small fly (*Maya pennibula*) which introduces its eggs into the heart of the shoots and occasions a loss of from eight to fourteen plants in a square of two feet. No remedy has yet been proposed for this pest, which, if not extensive, may be checked by plucking the injured ears, and burning them.

7053. Barley, besides other insect foes, has one peculiar to itself, in the shape of a small moth (*Thanaos mordax* L.) This fly deposits from twenty to thirty eggs on a single grain when hatched, each of the larva disperses, and selecting a grain for itself, enters from without, and has totally concealed should these moths be observed in a granary the injury may be stopped by carefully covering the grain, leaving a few handfuls exposed upon these the moths will deposit their eggs, and by rousing or destroying this small quantity, the rest may be saved from infection.

7054. Oats are subject to few diseases; but, like all other grain, the plants are liable to be destroyed by that universal devastator the wire-worm, of which a more particular account will be found in treating of insects universally injurious to vegetables.

7055. The diseases of peas are mildew and blight, but these are only occasional; its insect enemies, however, are formidable. The principal of these is the plant louse (Aphis) one species of which is peculiar to this plant. In the year 1814, the crops of peas throughout the whole kingdom was so much destroyed by it, that the produce was not more than the quantity sown; and many farmers burned their sown into their pen-folds, not thinking them worth gathering. (*Kirby and Spence* l. p. 177.) Beans are exposed to the same injury from another species of Aphis of a black colour, which begins at the top of the plant, and multiplies downwards. In both cases the most effectual remedy is to top the plants at an early period of the infection and burn the parts so gathered. This plan is likewise advantageous, as it improves both the quality and quantity of the crop. The earlier peas are sown, the better chance they stand of escaping this pest or if a small quantity of quick-lime is sprinkled upon them when they are a few inches high, experience has shown that the plants remain uninjured, while the Aphis is totally destroyed.

7056. The diseases of broad beans are the rust, honey-dew and mildew. The insects which infect it, and their eradication have already been noticed. (1826.)

7057. Turneps are subject to several peculiar diseases, and are the food of many noxious insects. On the first appearance of the cotyledon leaves, a whole host of little jumping beetles (*Haltia nemorum*), called by farmers the fly and blackjack, attack and devour them, so that the land is often obliged to be resown. An eminent agriculturist has calculated, that from this cause alone the loss sustained in the turnip crops of Devonshire in 1786 was not less than 100,000*l.* (*Young's Annals*, vii. p. 102.) Nearly as much damage is sometimes caused by a little weevil (*Ceuthoris contractus* Marsham), which in the same manner perforates a hole in the cotyledon, watering with lime water &c. may serve to check both these evils.

7058. The caterpillar of a saw-fly (*Phyllocolpa* L.), entirely of black colour appears on the plants so soon as they have protruded three or four rough leaves. These have sometimes been found considerable numbers particularly in 1785, when many thousand acres were, on this account, ploughed up. These caterpillars are simple when with to make ready by crows, rooks, and magpies, find these insects, whose food some have led them not to destroy but rather to encourage, these partial plagues, need not fear any great damage from them. It is therefore to be the most effectual way to remove or exterminate with lime has been strongly recommended.

7059. The caterpillar of the turnip-miner (*Pieris rapae* L.) is also much dreaded in great numbers nearly fly of the grub, which is much resembles the wire-worm, and which we have before noticed in (7054.), have been found just below the heart of a single bulb. These may in a great measure

be destroyed and destroyed, like the true wire-worm, which also does extensive injury to turnips. The small knave vermin, often observed on the roots, is inhibited by smoking holes of grubs, probably the larva either of *Ceuthoris contractus* L. or of *Phyllocolpa nemorum* L. two small weevils. These, however, did not seem to affect the growth of the plant.

7060. The noxious diseases of the turnip are the mildew (by some considered the effect of insects), distortion of the root (caused principally by the stems of lupins and peas), the efflux of the sap, and rotting, or wasting from rot and frost. None of these diseases, as far as it is known, admit either of prevention or cure; it under favourable circumstances of soil, culture, climate, and weather, they seldom occur; and therefore all that the cultivator can do is to prepare and remove his land properly and in the winter season supply water when the weather is dry.

7071. The hop is liable to many external and internal diseases by the first term we must be understood as alluding to injuries caused by insects, while those which belong to the vegetables are certainly internal. When the plants first emerge above the ground, they are infested by a small beetle, vulgarly called the flea. In a more advanced state the tops and branches are devoured by the hop Aphis, known to some by the name of the green fly while at the same period the roots are subject to the attack of the caterpillar

(fig. 971, a, d) that their form cannot be well distinguished without the aid of a magnifying glass; many of them resemble small scales or scabs fixed on the bark and shoots. One is entirely of a brown colour (*Coccus persicorum* a) when magnified (b) it somewhat resembles the tortoise beetle (*Cassida* L.), the legs and head being only discernible when the insect is turned on its back (c). Another (*C. fol. quercus*,

d, a, c) does much injury to the oak; while the *C. foli* attacks the twigs of the beech (g) and causes small round excrescences to appear; these are, however, very different from the gall apples of the oak (j), which are often found of a considerable size, and are produced by the *Cynips quercus* Riff. L. (h), or oak gall-fly and always contain either the larva or imperfect insect. The weevils (*Curculionidae*) form an exceedingly numerous family subsisting principally upon fruit, seed and grain. One of the largest found in this country is the nut-weevil (*C. nuceum*, fig. 970, e), the larva of which (c, d) are the maggots so frequently found in this fruit.

973. The insects injurious to plantations are less numerous in this country than on the Continent, yet we have two species whose devastations of late years have caused much alarm and extensive injury. The pine plantations in various parts of Britain have suffered from the great saw fly (*Urocerus gigas* Lest.), the larva of which feeding upon the heart of the tree, and boring in all directions, soon destroys it. Another small insect of the beetle kind (*Scolytus destructor* N., fig. 973, d magnified) is equally deadly to the elm and from being more common, and propagating very rapidly is more to be dreaded. The sudden destruction of a large proportion of the elms in St. James's and Hyde Parks has recently called the attention of government to this beetle; and at the request of the police magistrates, Mr. Maseley undertook to investigate the evil: the result of his observations have been since published (*Edinb. Phil. Journal*, No. 21). It appears that the female (a) may be found upon the trunk of the elm from March to September: she first penetrates through the bark, and then proceeds to form a passage between that and the wood, depositing her eggs during her progress on each side; when these are exhausted, the parent dies, and is often found dead at the extremity of the passage (b) thus formed. When the eggs are hatched, the young larvae immediately begin to feed by working nearly at right angles (c, d) from the path of the parent, each proceeding in a parallel direction and close to his neighbour: in this state they may be found in January. To stop this mischief as much as possible, Mr. Maseley recommends that the trees should be inspected twice a year: in summer, when the perfect insect is on the wing; and again in winter when infested trees should be cut down and burned, or uninfested by felling them to such a degree of heat as may destroy the larvae; or the bark may be covered with a mixture of tar and train oil, in March, to a certain height from the ground, applying this composition only to such trees as there are still hopes of preserving.

598. The cock-roach, called by some the black beetle (*Blatta orientalis*, fig 576, c) was originally imported from India, but is now naturalized in every temperate part of Europe. Like most of its tribe, it shuns the light, both natural and artificial. In the London houses, particularly in the rooms on the ground floor, it is very abundant, and indiscriminately devours bread, meat, flour and even its eggs. As soon as light appears they all scamper off as fast as they can, and vanish in an instant. It is said to be killed by devouring red wafers. The young are contained in a singular horny case (c) which is divided into a number of transverse partitions or chambers. It is rather flattened, and quite smooth except one side, which is toothed. The larva and pupa (b) are both without wings, and generally larger than the perfect insect (c).

7601 The house cricket (*Gryllus domesticus* L.) is sometimes as abundant in farm houses as the cock-roach is in those of London and other large towns, both insects devour every kind of food, and are often found drowned in pans of water, milk, and other fluids. It is said they will even attack stockings, or linen hung out to dry. They require great warmth, and are therefore mostly found in kitchens and bakehouses. Another species is peculiar to pastures, which in conjunction with the male cricket, feeds only upon roots: both these however are too local in this country to be very extensively injurious.

great pest to the winter provisions of the farmer, devouring butter, bacon, and all sorts of dried meats. This is principally done when the meat is in its larva or grub state (fig 570 f). When full fed it becomes a chrysalis (g) which ultimately changes into a small beetle (h) about a third of an inch long, of a dusky brown colour, with the upper half of the wing-cases whitish or ash colored, marked with black spots. The grub, from lying concealed in the meat, cannot be effectually removed, but by watching the time when the perfect insects appear they may then be destroyed, and a recurrence of the evil in a great measure prevented.

7602 The *beetle-grub* (*Dermestes lardarius* L.) is a voracious insect, devouring butter, bacon, and all sorts of dried meats, and all sorts of dried meats, and all sorts of dried meats. This is principally done when the meat is in its larva or grub state (fig 570 f). When full fed it becomes a chrysalis (g) which ultimately changes into a small beetle (h) about a third of an inch long, of a dusky brown colour, with the upper half of the wing-cases whitish or ash colored, marked with black spots. The grub, from lying concealed in the meat, cannot be effectually removed, but by watching the time when the perfect insects appear they may then be destroyed, and a recurrence of the evil in a great measure prevented.

7603 *Woolen clothing of every description, furs &c* are liable to be devoured by the larvae or caterpillars of no less than five distinct species of small moths. Most of these enclose themselves in little tubular cases of a silky texture, and are so well disguised externally by fragments of the stuff they feed upon as often to escape immediate observation. The receipts for preventing these ravages are numerous, but few of them can be depended upon. As a preventive, pieces of Russia leather or tobacco leaves, may be laid between the folds of garments (in drawers) which are not often used. If there is reason to fear the moths are in the house, these garments should be frequently opened and aired by exposing them to the sun. When furs of any kind are laid by for the summer they may either be sprinkled with snuff or camphor, and Russia leather or tobacco leaves put in the drawer or box. Should the moth actually have got into furs, the only way of checking the evil is to put them into an oven moderately heated, and by keeping them in this situation a quarter of an hour every grub will be effectually killed: the degree of heat may be ascertained, in the first instance, by putting in some common feathers, which should come out uninjured.

7604 The principal insects injurious to the agriculturist have now been enumerated: there are many others which feed upon cultivated vegetables and domestic stores, but in a less extensive degree. Let us not suppose, however, that these little animals have been created for our punishment or annoyance. We have but taken a view of one side of the picture: the other would show us innumerable benefits, either immediate or remote, which we derive from this race of beings. The silkworm the honey bee, and the common insect must not be forgotten: and myriads of others are created whose sole occupation during life appears to be that of devouring and keeping within due limits those tribes that are injurious and harmful to man.

### SUMMARY 6. Operations for subduing Insects.

605 The operations for destroying insects, or counteracting their injurious effects are various, and in most cases must be regulated according to the species. I have here already pointed out in treating upon the insects themselves, or of the particular plants upon which they feed. It only remains to offer such general rules as are more or less applicable to all destructive insects: these are of three kinds, preventive, palliative, and efficient processes.

606 The preventive operations are those of the best culture as relates to the choice of seed nor plant, soil, situation, treatment and climate: the four first are under the control of man, and an attention to them will undoubtedly lessen the risk of injured crops: but as regards weather, neither his foresight nor care can avail any thing.

607 The palliative operations are numerous: and such as are eminently successful may be considered as efficient: inasmuch as it rarely if ever happens that any insect can be exterminated even from one district: its numbers may be diminished but the species will still remain, although in such small numbers that its operations may escape notice. Most insects will be injured, and in part destroyed, by artificial bad weather: such as excessive wetness, stormy application of water with a syringe, and violent wind produced by shaking the tree or plant: many will thus be bruised, and others that are shaken to the ground can be destroyed. Insects may be further injured by watering the plants upon which they feed, either with tobacco or lime-water: or by scattering upon the leaves powdered quick-lime, soot, ashes, barley straw, &c. The smell of tar is particularly offensive to all insects, and the effects produced by the fumes of tobacco, sulphur, urine, &c. are well known. Hot water may be applied with much advantage. Water heated to 120 or 130 degrees will not injure plants whose leaves are fully expanded, and it may be increased to 200 for such as are without leaves.

608 Insects may be destroyed in a much more effectual manner by enticement, or placing in their way other food as a trap. The late noble and generous Sir Joseph Banks has the merit of having recommended and made known this most efficient method. It simply consists in cutting slices of potatoes or turneps, sticking them upon skewers, and then burying them near the seeds sown: the vermin will collect upon them during night, and by examining them every morning, vast numbers may be destroyed: this plan has been very advantageously tried with the wire-worm, and no doubt would be equally beneficial in clearing all crops that are attacked by under ground feeders. Mr Kirke states, "that it was very successfully employed in 1812, by J. M. Rodwell, Esq of Barham Hall, near Ipswich, one of the most skillful agriculturists in Suffolk, to preserve some of his wheat fields from the ravages of a small grey slug, which threatened to demolish the plant. Having heard that turneps had been used with success to entice the slugs from wheat, he caused a sufficient quantity to draw eight acres to be got together: and then, the tops being divided and the apples sliced, he directed the peccos to be laid separately, dressing two stalks with them, and omitting two alternately till the whole field of eight acres was gone over. On the 24th

having standing he employed two women to examine and free from the slugs (which they did by a searching the turn and slugs; and when cleared, they were laid upon those stretches that first lapsed the day before. It was observed invariably, that in the stretches dressed with the turnips, no slugs were to be found upon the wheat, or crawling upon the land, though they abounded upon the turnips; while, on the undressed stretches, they were to be seen in great numbers both on the wheat and on the land. The quantity of slugs thus collected was near a bushel. Mr. Rodwell is persuaded that by this plan, he saved his wheat from essential injury (*Kersey and Spencer, Ist to Entomology* i. p. 181. note.)

977

769. The turnip net (fig. 977) is an instrument invented by Mr. Fard of Banston in Norfolk. It is the most successful expedient that has yet been thought of for the capture and destruction of the little beetles called by farmers the black-jack, and by hop-growers the flea. It consists of two pieces of stout wood, the ends of which, at one extremity are fixed into a handle in a forked direction: the other ends are left thick and curved upwards, for the purpose of passing the instrument smoothly and easily over the surface of the ground. Towards this end, the sticks are connected by a cross-bar formed by a thin iron rod, thus may be taken on and off at pleasure; these three sides constitute the frame work for supporting a long and ample bag, made of strong glazed calico. The method of using it is by the operator showing it before him on the ground, over the tops of the turnips or other plants; by this means the insects that are upon the leaves fall into the bag, which may be occasionally shaken during the process, so as to bring them to the bottom (which is made narrow) where they will remain. Vast quantities of insects, which from their smallness and agility defy hand-picking, will be thus captured. The turnip net may be made either large or small, perhaps two feet and a half for the side sticks is the best length. It being obvious that the wider they are apart, the greater space will be struck at once.

770. The lime-duster (fig. 978) is a recent invention by Mr. Samuel Curtis of Glasenwood, near Coggeshall, Essex, and has been used by him with great success in throwing pulverised quick-lime over apple trees infected by caterpillars and other insects. His orchard, containing many thousand fruit trees, and occupying fifty acres had been for many years completely divested of most of their foliage and young fruit in the spring months. Washing the stems and branches with lime and water (as might have been expected) was found ineffectual for the destruction of insects which hid only on the young buds and leaves. The instrument in question consists of a canister twelve inches long, seven inches wide at its broadest, and four inches on its narrowest part; the handle (a) is five inches and a half long. The top of the handle is fitted with a cap (b), which is put on when the lime is to be thrown on low trees, but when high trees are to be operated upon, the cap is removed, and a pole of sufficient length to reach the height required is inserted into the handle. Quick lime pulverised (and often sifted through a fine sieve) is put into the canister and shaken over the young foliage just as it was expanding. The time for doing this is in the dew of the morning, or whenever the leaves are damp and if there should be a gentle breeze, sufficient to carry the dust obliquely through the head of each tree, it is the more quickly performed. Under favourable circumstances of this nature, Mr. Curtis says, "I found that three men, provided with the powder in a large box on a light wheelbarrow could dress from two to three thousand trees in a day when the wind changed, I had the trees dressed on the other side. Although used ever so freely no person need fear any injury from the caustic quality of the lime, on the most delicate and fresh expanding foliage; it is only prejudicial to insects of all kinds, and to dead vegetable matter;" (*Hort. Trans.* vol. vi. p. 2. page 194.) We know not whether the lime-duster has

978

ever been tried upon hop plantations infected by the green fly or plant louse but it appears to us equally well adapted to effect a great destruction among those insects.

771. *Grass of all deceptions* that is infected by weevils, or by the grubs of other insects, should be spread in the sun, and frequently turned: the warmth will bring the animals out of the grass, and considerable numbers may be destroyed. It has been said that they may be kept away by stirring boughs of alder or branches of hawthorn among the grain, but this wants confirmation.

772. *Hand-picking*, independent of the foregoing methods, is too tedious and too ineffectual for general adoption in large crops, but is probably the best that can be resorted to in gardens or small enclosures. In this way the different voracious vegetables, and the common and low kinds of fruit trees, as currants, gooseberries, &c. may be cleared of a vast number of caterpillars.

773. *Catching the pyralis insect* is undoubtedly the most certain plan for preventing a return of the same injury the following year for the death of one female will cut off a generation of a hundred larvae, but from the difficulty that attends an extensive adoption of this plan, it is not likely to be much attended to.

#### SECT. IV. Worm-like Animals injurious to Agriculture.

774. *Of worms* (*Vermes L.*) generally so called, there are but few which may be considered as injurious to agriculture. The principal of these are the various species of slug (*Arion L.*, *Limax L.*) and the large and small snails (*Helix hortensis* and *monstrilis L.*), mostly found in garden plantations. The earth or dew worm (*Lumbricus terrestris L.*), unless existing in great numbers on a single spot, cannot be ranked among injurious animals, notwithstanding the prejudices of farmers and gardeners against them. With out worms the earth would soon become hard, cold, incapable of receiving moisture, or of giving nourishment to roots: they are, in fact, the great promoters of vegetation, by boring, perforating, and loosening the soil beneath, and by raising it above their heads, which is thrown up into lumps called worm casts. The wire-worm does not belong to this tribe, but is the larva of a small beetle already noticed.

775. *Worms of the slug kind* are without shells. There are several species inhabiting Britain, all of which subsist on leaves, roots, and vegetables. The most common is the *Limax agrestis* (fig. 979 a), of which there are several varieties injurious to the agriculturist and gardener: they devour the young shoots of turnips, wheat, and indeed all kinds of grain frequently to a ruinous extent: their eggs (b) are small, round, of a semitransparent whiteness, and are deposited in the earth. The methods of destroying or confining the parties intended have been already described.

776. The slug slug (*Taraxacum Maderi F.*, c) is a native of Tuscany, and has likewise been found in several parts of France and Spain; it has recently been discovered in some gardens near Bristol, by Mr. Miller, of that city. It is a highly voracious animal, remarkable for feeding upon earth worms, and may, therefore, be beneficially introduced into such gardens as are overstocked by that otherwise

small animal. It is readily distinguished from all other slugs in this country by having a thin oval shell

(e) affixed to the hinder part of its body. Slugs in general are equally suited by cabbage leaves, scattered near such garden vegetables as they appear to injure most.

7707 *Slugs*, are slugs covered by a shell. The two species most prejudicial to cultivated vegetables, are the garden snail (*Helix aspersa* Gm.) and the variegated snail (*Helix nemoralis*, *Helix*), both these seek the same description of food and are equally injurious, as slugs and, like them, may be enticed by cabbage leaves and other juicy vegetable refuse.

## PART IV

### STATISTICS OF BRITISH AGRICULTURE.

7708. AFTER having considered agriculture as to its history as to the scientific principles on which it is founded, and the application of these principles to the different branches of practice it remains only to take a statistical survey and estimate of its present state and future progress in the British Isles.

## BOOK I.

### OF THE PRESENT STATE OF AGRICULTURE IN THE BRITISH ISLES.

7709 *The present state of British Agriculture*, as to knowledge and the details of practice, has been the subject of the former PARTS of this work but its importance in the general economy of society can only be learned by a view of the manner in which it is actually carried on, the modifications to which it has given rise in the pursuits of those who have embraced the art as a source of livelihood; of the kinds of farms cultivated by different orders of agriculturists of the principal practices of each of the different counties of Britain and Ireland as to agriculture, of the British authors who have written on the subject, and of the professional police and public laws relative to husbandmen and agriculture.

## CHAP. I

### Different Descriptions of Men engaged in the Practice or Pursuit of Agriculture.

7710. *Agriculturists* may be arranged as operators, or serving agriculturists, dealers, or commercial agriculturists, counsellors; professors, or artists, and patrons.

#### SECT. I Operators or serving Agriculturists.

7711 *The lowest grade on the scale of this class is farm labourers* who may be either men, women, or children, and either local residents or periodical tenants for particular labours, as hay-making &c. or itinerant workmen for taking jobs, as ditching, stocking, &c. None of this class of operators are supposed to have received any other professional instruction than what they have derived casually or from observing others.

7712. *Apprentices* are little known in agriculture but they occur sometimes, either as the children of other operators, whose parents bind them a certain number of years, during which they are to work for their food and clothes, and fit or fit to be received at the end of the term according to conduct; or sons of nobler persons, who pay a premium for the instruction to be received, and fit learning with the master. The former class of apprentices generally look forward to being ploughmen, shepherds, head ploughmen, or inferior bailiffs the latter to being first bailiffs, stewards of estates or to farming on their own account. Farish boys are sometimes bound apprentices of the first class, and various nobleman's sons from almost every kingdom of Europe have been included in the second.

7713. *The sown four-year-olds* is a little known in agriculture as apprentice. Those who among to that term are the professional operators of a farm, such as ploughmen, cattle herds, shepherds, and hedgers. These rank definitely above labourers of all work. A ploughman may not usually be considered as of the rank of an apprentice till he can fur or set out ridges, and after he can do this as of the rank of journey men till he can stack and sow. He may then be considered as a master of his art, entitled to work the best pair of horses, and at twenty-five or thirty years of age, to enter into the marriage state.

7714. *A hedger* is a professional operator who may be considered as ranking with a master ploughman. His business is to plant, clear, prune, cut, lay, plash, and repair hedges, to prune forest and orchard trees, and effect other operations with hedges and plants on the farm. In Dorsetshire hedges are generally very intelligent men, and keep the fences on the farms in the border counties in excellent order, and the hedger trees handsomely pruned.

7715. *A woodman* is an operator employed to prune trees and manage hedges, and is of the same rank and requires the same kind and degree of professional knowledge as the hedger. Generally he is more conversant with backing trees for the timber, converting copsewood and measuring timber than the other, being more engaged with woods than hedges.

7716. *A head ploughman*, on small farms, is to be considered as the bailiff in the absence of the master. He works the best pair of horses, and assists the master in stacking and sowing. On larger farms, where a regular bailiff is kept, there is also a head ploughman, who acts as substitute for the bailiff in his temporary absence, as far as operative and overlooking operations, but not as money matters or contracts.

7717. *A farm bailiff*, or should be, a person of tolerable education, who understands accounts, management of work, land, and timber, and can draw up agreements for hiring servants. He should have practised every part of farming himself, from tending poultry, swine and sheep, to stacking and sowing. When employed by a gentleman, or one who has no skill in farming, he should not be under twenty-five years of age, but a farmer's bailiff need not exceed twenty-one years, to be considered as a sort of apprentice, and will be directed in all leading matters by his master.

7718. *A landish gardener* or gardener and grave, as they are called in some places, is a sort of hybrid upper servant, who seldom excels either as a farmer or a gardener, and is only fit for situations of limited extent, and an indifferent style of performance.

7719. *The forester* or head woodman is to the woods of an estate what the bailiff is to the farm lands in hand. He directs and superintends the woodmen and their labourers, in planting, rearing, and pruning plantations, and in the felling of timber or copse, bark, charcoal making, and in short every thing connected with timber, trees, copse, or hedges.

7720. *The land steward* (*Factor* Scotch, *Factor* Fr., *Factor* Ger., and *Fattore*, Ital.) is to a whole estate what a bailiff is to the demesne or a particular farm. His business is to control the managers of the lands in hand, as the forester, gardener, bailiff, &c., to see that farmers fulfil the covenants of their leases to attend to repairs, roads, public and parochial matters in behalf of the landlord, and generally to receive rents.

7721. *Under stewards* or steward's bailiffs, as they are called, are assistants to the main steward or have the care of detached estates, containing a few farms or woods.

7722. *Demesne stewards* are such as are kept chiefly for regulating the affairs of demesne lands, that is, lands surrounding the mansion in hand, or of an estate of small size, where all the lands are in hand, but where an extensive establishment of horses, servants, a large garden, &c. are kept up. Here the steward performs the duties of bailiff, forester, and in some degree of house-steward, by his connection with the stables and game keeper, and other domestic rural matters.

7723. *Court farmer* (*Hoffmeyer* Ger., *Grangero de la corte* Span., *Agronomo de la corte* Fr., and *Fattore della corte*, Ital.), may be considered the highest step, the summum bonum of agricultural servitude. The late Ramsey Robinson Esq. was bailiff to Geo. III. his sister Miss Robinson, was royal dairy-woman, and Sir Joseph Banks royal shepherd.

## SECT. II. Commercial Agriculturists

7724. *The lowest grade here is the jobbing farmer*, who keeps a team, a cart, plough, pair of harrows, and probably one or two hand implements. He hires himself by the day, week, or by the acre to plough, sow, or labour, the small spots of ground of tradesmen who keep a cow but no labouring stock, or to assist farmers who are weary with their labours. The contractors for executing works devised by the agricultural engineers (7764), though widely separated in point of wealth from the common jobber, yet belong to the same species, both agree in selling their labour and skill in a raw state, not when manufactured to produce like the other commercial agriculturists.

7725. *Miscellaneous agriculturists* are of two kinds, such as take grounds for the culture of one or two crops of particular sorts of plants, as wood, flax, &c. (8633) and such as travel with a plough and pair, &c. to teach that operation to young farmers or their servants, a practice at one time carried on in Ireland under the patronage of the Dublin Society.

7726. *Cottage farmers* are such as possess a cottage and an acre or two of land, which they may either keep in aration or pasture, disposing of the corn, green crops, or dairy produce in various ways, according to local circumstances.

7727. *Poultry farmers*, such as devote themselves chiefly to the breeding, rearing, and fattening of poultry, and the growing of feathers and quills.

7728. *Garden farmers* are such as possess lands near large towns or sea-ports, and grow the commoner garden vegetables, as peas, onions, cabbages, &c. for the market, or herbs for the distillers and druggists.

7729. *Small farmers* or small farmers who devote themselves wholly to the growing of garden seeds for the London seedsmen, and for the distillers. They are to be found only in a few counties in the central and southern districts of England, and chiefly in Kent and Essex. (See *Notes of Gard.* edit. 7/50.)

7730. *Orchard farmers* are such as farm grass or arable orchards, sometimes joined to hop lands and garden farms, often with a small dairy with rearing of poultry, rabbits, &c. and sometimes with the breeding and feeding of dogs, the latter a very lucrative branch when well understood.

7731. *Hop farmers*, such as make hops a principal article of cultivation, to which are sometimes joined garden and orchard farming.

7732. *Milk or cow farmers*, such as keep cows for selling their milk in an unmanufactured state. These farmers are of course limited to populous neighbourhoods. Cow-keepers differ from cow farmers, in having their establishments in towns, and in purchasing, not growing, their own provender.

7733. *Dairy farmers*, such as keep cows and manufacture their milk into butter or cheese. These are most common in rich inland districts, as Cheshire, part of Gloucestershire, Lancashire, &c.

7734. *Sheepers*, farmers whose chief business consists in buying, feeding, and selling cattle and sheep. Their farms are usually in low pasture, and they are more commonly fencers than breeders. The most extensive in England are in Lancashire and Lincolnshire.

7735. *Stock farmers*, such as devote themselves to breeding and rearing different kinds of live stock, especially horses and cattle. They are most common in Yorkshire.

7736. *Sheep farmers*, breeders who devote themselves chiefly to the sheep and cattle families. They are common in the border counties, in Wales, and in the Highlands.

7737. *Hay farmers* are confined to a small district round London, where they grow chiefly natural or meadow hay for the London coach and saddle horses, and for cow keepers.

7738. *Cart farmers*, as opposed to hay, dairy, grazing, and breeding farmers, is a term employed to such as occupy lands more adapted for the plough than for pasturage, as arable clays and loams.

7732. *Wood-farmers*, such as rent woodlands, to be periodically cut for fuel, bark, fence-wood, charcoal, or other purposes.

7733. *Gravel-farmers*, such as rent quarries of lime or other stone, gravel-pits, chert-pits, marl-pits, &c.

7741. *Mine-farmers* or master miners or mine-holders, such as rent coal-mines, or mines of iron, lead, or other metals.

7742. *Salmon or river-farmers* or fishery renters, such as rent rivers or ponds for the sake of their fish.

7743. *Commercial or professional farmers*, such as farm lands for profit. Those who farm an extent of

good land under one hundred acres are considered small farmers; under three hundred acres, middling

farmers; above and under five hundred acres, large farmers and exceeding that quantity extend to

farmers; a very proper title, for few arable lands can be profitably cultivated to a greater extent in one

farm or by one establishment than five hundred acres, and those which exceed that quantity are generally

breeding or other stock farms, characterised by their extent.

7744. *Gentlemen farmers*, are professional farmers on a large scale, who do not associate with their minor and personally working brethren but who affect in their style of living the habits and manners of independent men of gentlemen. It is a character extremely liable to ridicule by the vulgar yeoman and purse-proud farmer on the one hand, and those persons who are gentlemen by profession and men of family on the other.

7745. *Town-farmers* small proprietors who farm their own lands but yet aspire not to the manners and habits of gentlemen.

7746. *Farming landlords* proprietors who farm their own lands on a large scale.

### SECT. III. *Agricultural Counsellors, Artists, or Professors.*

7747. *The land-measurer* is the lowest grade of agricultural artists: he is very often the village school-master and is called in to measure work done by the job as mowing reaping hedging trenching, &c.

7748. *The agricultural salesman* is a person who attends at fairs markets, &c. and acts as agent to buyers and sellers of corn and cattle. There are also salesmen purposely for hay and straw others for green food, turkeys, potatoes, &c.

7749. *The appraiser or valuer of farming-stock*, comes next in order. This professor values the live and dead stock, and sheep, villages, manures, &c. and estimates also the remainder of leases between out-going and incoming tenants, or between tenants and their landlords. Occasionally the appraiser is employed to value lands, but this is generally the business of the land-valuer.

7750. *The land-surveyor* generally confines his avocations to the measuring and mapping of lands or to their subdivision or the arrangement of fences and other lines but sometimes he joins the business of appraiser and valuer and even timber-measurer.

7751. *The timber surveyor and valuer* confines himself in general to the measurement and valuation of fallen or standing timber: he also measures and estimates the value of bark, aggrata, roots, charcoal, ashes, willows, hoops and various other products of ligneous plants.

7752. *The land-valuer* not only values the rental, but the price of the simple of lands, buildings, woods, quarries, and waters. He does not often meddle with metallic or saline mines but he sometimes values fisheries, stone and lime quarries, brick-earth gravel chalk &c. This profession requires not only a general knowledge of agriculture in the most extensive sense of the word but a very extensive acquaintance with the country in which the property lies, and great experience in business. There are local and general land-surveyors and land-valuers: the general professors live in the capital cities or in the metropolises, and generally unite the business of land-agent.

7753. *The land-agent* may or may not be a land-valuer but at all events he should possess the knowledge of the value in an eminent degree. His business is to effect the transfer of property by purchase, sale, hiring, or letting; and also to collect rents, and often to re-let farms, and effect other business belonging to the land-valuer. Land-agents are very frequently attorneys, who know little of agriculture, but who save their employers the trouble of employing both a land-steward of superior abilities, and a lawyer to draw up agreements and leases. It is the opinion of the best informed agriculturists both of Britain and France, that the employment of attorneys as land-stewards and agents has been one of the chief causes of the retardation of agriculture throughout Europe. Christy has clearly shown how this cause has operated in France and Italy; and Dr Henderson Arthur Young Marshall, and various others, have deprecated its influence in Britain. The love of precedent, which these men cannot abandon from habit the love of litigation to which they adhere from taste and interest and the ignorance of agriculture, from the nature of their education are the causes that have counteracted the tendency to change and amelioration.

7754. *Of agricultural engineers* there are considerable variety. The *draughtsman*, for laying out drains and water works; the *irrigator* for watering the surface of grass-lands the *road engineer* for laying out roads the *mineral surveyor* for searching for measuring mapping, and valuing in new and minerals; the *coal surveyor* for estimating the value of coal works; the *rural architect* for designing and superintending the execution of agricultural buildings; and the *hydrographical and canal engineers* for canals, harbours, mills, and the greater water works.

7755. *The veterinary surgeon*, or agricultural doctor is to be considered as a rural professor and as subordinate grades, may be enumerated the farrier *Ferrero* Fr. *Ferrajo* Ital. a smith from *ferro* Lat. iron), cowleech, and castrator or gelder.

7756. *The agricultural draftsman*, or artist by way of eminence, is employed in designing and painting live-stock, implements, plants, and cultivated scenery: the plans of farms are taken by the land surveyor designs of buildings made by the architect, and new inventions in machinery and implements are drawn by the inventor, whether millwrights or agricultural mechanists.

7757. *The agricultural author* may be considered as the most universal kind of agricultural counsellor since his province includes every branch of the art, and comprehends times and practices past present, and to come. The simplest variety of this species is the author of single papers in magazines, or the transactions of societies: the most extensive, he who embraces the whole of the subject; and the most valuable, he who communicates original information.

7758. *The professor of agricultural science* (*Professeur d'Agriculture ou d'Economie Rural*, Fr. *Hochlehrer von Ackerbau*, or *H von Landwirtschaft* Ger.; *Professor d'Agricultura*, Span. and *Professore d'Agricoltura*, Ital.), when appointed by a permanent or national institution may be reckoned the highest grade of agricultural counsellor since he is not a self-constituted instructor like the author; but constituted by competent judges as capable of instructing the public. The first public professor of agriculture appointed in Britain was Dr Cresswell of the University of Edinburgh about 1790; and the next Sir Humphrey Davy, Lecturer on Agricultural Chemistry to the Board of Agriculture about 1807 both highly eminent as agricultural counsellors, independently of their other merits. There are agricultural professors in Dublin and Cork. In almost every University on the Continent there is an agricultural chair and in some of the German and Russian Colleges there are chairs for gardening (*Gartenbau*) husbandry (*Haustwissentchaft*), and rural architecture (*Landbaukunst*).

### SECT. IV. *Patrons of Agriculture.*

7759. *Every man being a consumer of some description of agricultural produce, may be considered a promoter of the art by causing a demand for its productions. The more valuable consumers are such as*

here on the best bread, butcher's meat, fowls, and dairy products and the greatest of all patrons, both of agriculture and gardening, are such as these sunguously every day.

7760. *Amateur agriculturists*, lovers of agriculture, promote the art by the appliances they bestow on its professors; of which, to a certain extent, they become purchasers, as of farming books, prints of cattle, implements, &c.

7761. *Connoisseurs, critical or skilful lovers of agriculture*, promote the art in the same way as the amateur but much more powerfully, in proportion as approbation founded on knowledge is valued before that which arises chiefly from spontaneous affection. By the purchase of books, models, attendance at agricultural exhibitions, &c., connoisseurs encourage both connoisseurs and commercial agriculturists. Sometimes, also, by their writings, of which Sir John Sinclair is an eminent example.

7762. *Amateurs of agriculture*, whether of the serving class, as bailiffs, stewards, &c. or of the order of professors or artists, are obvious encouragers of the art.

7763. *Amateur farmers* are patrons on the same principle as employers, and sometimes, also, they effect improvements, or communicate valuable information to the public. Cline, the late eminent surgeon, and the late physician, Dr. Barry were eminent examples.

7764. *Noblemen and proprietors of farms* are conspicuous patrons. They render the art fashionable and by the general attention so directed, and consequent occupation of many minds on the same subject, new ideas are elicited, and dormant talents called forth and employed. The names of Russell, Coke, Curwen, and Somerville stand prominent among this species of patrons, and many others might be added.

7765. *Meliorists and gentlemen improvers*, whether by planting, building, road-making, establishing villages, churches, harbours, &c. are evidently greater patrons of agriculture than noblemen farmers, since their improvements affect society more extensively. As decidedly at the head of this species of patron may be mentioned the late Duke of Bridgewater and the present Marquess of Stafford, and to these names might be added a number of others.

## CHAP. II.

*Different Kinds of Farms in Britain relatively to the different Classes of Society who are the Occupiers.*

7766. *Cottage farms* form the first link in the chain of temporary terrestrial possessions. They consist of one or more acres appended to a cottage for the purpose of enabling the occupier to keep a cow if any part of this farm is in arable, the labour is either hired or some jobbing agriculturist, or done by spade or two or more cottagers join together and form a team of their cows, with which and implements borrowed from the village carpenter or smith they accomplish their labour.

7767. *Farms of working mechanics*. These are larger than the former and are rented by country blacksmiths, carpenters, &c. who often keep a horse or a pair of horses. Both this and the former sort are very often injurious to the occupiers, by drawing off their attention from their principal source of income though it must be confessed at the same time that the idea of occupying land, and raising one's own corn, clover, milk, butter, eggs, pulses, &c. is highly gratifying gives a sort of sense of property and has an air of independence and liberty highly valued by men in general.

7768. *Farms occupied by village tradesmen and shopkeepers*. Many of these men such as bakers, butchers, grocers, &c. keep a horse at any rate by renting a few acres they are able to keep another and add a cow and other minor species of live stock. The attention required from the master forms a healthful recreation, and agreeable variety of occupation and if this recreation does not interfere with main pursuits, there is a gain of health and respectability.

7769. *Farms occupied with a view to profit by town and city tradesmen*. These are on a larger scale than the last, and held by stable keepers, cow keepers, butchers, corn-dealers &c. They are often of considerable size mostly under grass, and managed by bailiffs. Arable farms in such hands are rarely well managed, as every thing is made to depend on nature, but as less skill and vigilance is required in managing grass-lands, hay or pasture farms of this description are generally well managed, and consequently productive. They are seldom however profitable, and it is only because the renter runs the double risk of grower and consumer, has some enjoyment in the idea of the thing, and some increase of health from the requisite work to it, that he finds it suitable to continue his farming operations.

7770. *Farms occupied by city tradesmen for recreative enjoyment*. These are of various descriptions, and generally managed by bailiffs. They may be considered as affording recompense only by the amusement, exercise, and health which they afford, and the interest in country matters which they excite. Many a worthy man thus throws away almost at random, on agriculture, what he has gained by trade with the greatest industry and frugality often joined to skill and ingenuity. When the farm proves well, the tradesman is almost tempted to sell his trade and turn farmer for good (as it is called) & so a principal occupation and often ends in impoverishing or even ruining himself.

7771. *Farms attached to the villas and country houses of wealthy citizens*. On these the wealthy citizen pays at agriculture, aided by a skilful manager or bailiff. Immense sums of money are thus expended in the neighbourhood of large towns many ingenious practices are displayed and though nothing in the way of profit is ever expected to be gained, yet on the whole an attention to agriculture is excited in the minds of wealthy commercialists, who buy books on the subject, procure bailiffs, approved implements and breeds of stock, and thus give encouragement to these and other productions connected with the subject. The history of farming for the last twenty years round Edinburgh Liverpool and London, affords some curious, singular, and extravagant examples of this description of farming, and some of a much more judicious description.

7772. *Domanial farms*, or such as are occupied by the landed proprietors of the country. These are of a great many different kinds some regularly appended to the park, some comprising a part of the park separated by temporary fences and others taken into occupation without regard to situation. Some proprietors take all the farms on their estate successively into their own hands cultivate them for a few years, bring them into excellent order, and then let them to farmers. Much good is often done by proprietors occupying land themselves new practices, and new kinds of vegetation and live stock, are exhibited and disseminated; and the landlord himself, being instructed by experience in the practice of farming, is better able to judge what his land should let for and more likely to appreciate good tenants and sympathize with the losses of his farmers in bad seasons. Add also, that a proprietor in this way procures better butcher's meat of every kind than he could generally purchase in the neighbouring markets, and, if he chooses, better legumes and roots, and even better cabbage and other culinary vegetables than he could grow in his kitchen garden. The bailiffs on such farms are, or ought to be, well educated men, brought up to farming in the best discipline. They should be well paid, and have sub-bailiffs under them. The establishments of Russell, Coke, Curwen, Althorpe, &c. are or were among the most complete in this kind of farming.

7773. *The farms of professional farmers*. It must be obvious that this class includes more than nine tenths of all the farms in the country. They are of every description of soil, climate, situation &c. which the country affords, of all manner of size, according to the demand created by such as follow farming as a business; and either devoted to the general purposes of corn and cattle, or more particularly the poultry

**794. HERTFORDSHIRE.** A surface of 500,000 acres, studded with hills, hills, and minor swells of various heights and dimensions, almost every where of a rich soil, devoted exclusively to agriculture, and highly productive in corn, wheat, straw, oats, hay, and timber. The most distinguished cultivator in the county is T. A. Knight, Esq., known in agriculture by his treatise on the Apple and Pear, many valuable papers in the Transactions of the Royal Society and communications to the Board of Agriculture, and in gardening by numerous essays and improvements, and his honorable office of President of the Horticultural Society (Clark's *Hertfordshire*, 1794. Duncanson's Report 1808. Marshall's *Re. new*, 1812.)

#### 1. Geographical State and Circumstances.

Climate, remarkably healthy, even while the coldest; warm at midday, and short heat.

**Soil.** A variety of soil, generally fertile, except some spots of the county. The heaviest soils, of which there are a large tract between Hemel Hempstead and Letchworth; the lightest lands in the south-east about Watlington and Epping in the Epsom hills, have the prevailing position there in former times.

**Minerals.** From this in the county districts, but none appear to be of great value. But and yellow ochre, pipe-clay and fuller's earth, but only the latter worked for

Wheat straw, almost equal to the Wye, but, owing to the wet and flood-prone, not so abundantly as formerly.

#### 2. Property.

**Grass Meadows.** Date of Maturity. Part of Oxford, Part of Essex, Part of G. Cornwall, &c. The largest proprietors. Their estates divided into farms of from 200 to 400 acres. A number of estates from 400 to 1000 are common, and are generally well managed by their owners, and cultivated and managed in good style, with a view to the introduction of the best agricultural practices. The tenants of grassland and harvest fields are in a few places, but are generally satisfied with it.

#### 3. Buildings.

Some fine ones of proprietors as Horn Lane, Hemel Hempstead, Hertford Castle, &c. Old stone houses of wood. It is agreed, and placed some good new ones as the Grays' Hospital and other estates. The houses are generally of a better construction. The houses lately built by new cottages, for the Hertford market, with a view to the poor.

#### 4. Occupations.

Small farms on the decline. Few opportunities now by which an industrious man could acquire 500, or 1000, or 1500, or 2000, or 2500, or 3000, or 3500, or 4000, or 4500, or 5000, or 5500, or 6000, or 6500, or 7000, or 7500, or 8000, or 8500, or 9000, or 9500, or 10000, or 10500, or 11000, or 11500, or 12000, or 12500, or 13000, or 13500, or 14000, or 14500, or 15000, or 15500, or 16000, or 16500, or 17000, or 17500, or 18000, or 18500, or 19000, or 19500, or 20000, or 20500, or 21000, or 21500, or 22000, or 22500, or 23000, or 23500, or 24000, or 24500, or 25000, or 25500, or 26000, or 26500, or 27000, or 27500, or 28000, or 28500, or 29000, or 29500, or 30000, or 30500, or 31000, or 31500, or 32000, or 32500, or 33000, or 33500, or 34000, or 34500, or 35000, or 35500, or 36000, or 36500, or 37000, or 37500, or 38000, or 38500, or 39000, or 39500, or 40000, or 40500, or 41000, or 41500, or 42000, or 42500, or 43000, or 43500, or 44000, or 44500, or 45000, or 45500, or 46000, or 46500, or 47000, or 47500, or 48000, or 48500, or 49000, or 49500, or 50000, or 50500, or 51000, or 51500, or 52000, or 52500, or 53000, or 53500, or 54000, or 54500, or 55000, or 55500, or 56000, or 56500, or 57000, or 57500, or 58000, or 58500, or 59000, or 59500, or 60000, or 60500, or 61000, or 61500, or 62000, or 62500, or 63000, or 63500, or 64000, or 64500, or 65000, or 65500, or 66000, or 66500, or 67000, or 67500, or 68000, or 68500, or 69000, or 69500, or 70000, or 70500, or 71000, or 71500, or 72000, or 72500, or 73000, or 73500, or 74000, or 74500, or 75000, or 75500, or 76000, or 76500, or 77000, or 77500, or 78000, or 78500, or 79000, or 79500, or 80000, or 80500, or 81000, or 81500, or 82000, or 82500, or 83000, or 83500, or 84000, or 84500, or 85000, or 85500, or 86000, or 86500, or 87000, or 87500, or 88000, or 88500, or 89000, or 89500, or 90000, or 90500, or 91000, or 91500, or 92000, or 92500, or 93000, or 93500, or 94000, or 94500, or 95000, or 95500, or 96000, or 96500, or 97000, or 97500, or 98000, or 98500, or 99000, or 99500, or 100000, or 100500, or 101000, or 101500, or 102000, or 102500, or 103000, or 103500, or 104000, or 104500, or 105000, or 105500, or 106000, or 106500, or 107000, or 107500, or 108000, or 108500, or 109000, or 109500, or 110000, or 110500, or 111000, or 111500, or 112000, or 112500, or 113000, or 113500, or 114000, or 114500, or 115000, or 115500, or 116000, or 116500, or 117000, or 117500, or 118000, or 118500, or 119000, or 119500, or 120000, or 120500, or 121000, or 121500, or 122000, or 122500, or 123000, or 123500, or 124000, or 124500, or 125000, or 125500, or 126000, or 126500, or 127000, or 127500, or 128000, or 128500, or 129000, or 129500, or 130000, or 130500, or 131000, or 131500, or 132000, or 132500, or 133000, or 133500, or 134000, or 134500, or 135000, or 135500, or 136000, or 136500, or 137000, or 137500, or 138000, or 138500, or 139000, or 139500, or 140000, or 140500, or 141000, or 141500, or 142000, or 142500, or 143000, or 143500, or 144000, or 144500, or 145000, or 145500, or 146000, or 146500, or 147000, or 147500, or 148000, or 148500, or 149000, or 149500, or 150000, or 150500, or 151000, or 151500, or 152000, or 152500, or 153000, or 153500, or 154000, or 154500, or 155000, or 155500, or 156000, or 156500, or 157000, or 157500, or 158000, or 158500, or 159000, or 159500, or 160000, or 160500, or 161000, or 161500, or 162000, or 162500, or 163000, or 163500, or 164000, or 164500, or 165000, or 165500, or 166000, or 166500, or 167000, or 167500, or 168000, or 168500, or 169000, or 169500, or 170000, or 170500, or 171000, or 171500, or 172000, or 172500, or 173000, or 173500, or 174000, or 174500, or 175000, or 175500, or 176000, or 176500, or 177000, or 177500, or 178000, or 178500, or 584000, or 584500, or 585000, or 585500, or 586000, or 586500, or 587000, or 587500, or 588000, or 588500, or 589000, or 589500, or 590000, or 590500, or 591000, or 591500, or 592000, or 592500, or 593000, or 593500, or 594000, or 594500, or 595000, or 595500, or 596000, or 596500, or 597000, or 597500, or 598000, or 598500, or 599000, or 599500, or 600000, or 600500, or 601000, or 601500, or 602000, or 602500, or 603000, or 603500, or 604000, or 604500, or 605000, or 605500, or 606000, or 606500, or 607000, or 607500, or 608000, or 608500, or 609000, or 609500, or 610000, or 610500, or 611000, or 611500, or 612000, or 612500, or 613000, or 613500, or 614000, or 614500, or 615000, or 615500, or 616000, or 616500, or 617000, or 617500, or 618000, or 618500, or 619000, or 619500, or 620000, or 620500, or 621000, or 621500, or 622000, or 622500, or 623000, or 623500, or 624000, or 624500, or 625000, or 625500, or 626000, or 626500, or 627000, or 627500, or 628000, or 628500, or 629000, or 629500, or 630000, or 630500, or 631000, or 631500, or 632000, or 632500, or 633000, or 633500, or 634000, or 634500, or 635000, or 635500, or 636000, or 636

size of drainage. It is possible, however, where low, or even where land is high, to provide the garden in such a manner that there may be little inconvenience; and sometimes these transplanting facilities may do better together than two.

4. *Drainage.* On the borders of Wales the farms are small, many not exceeding twenty acres; on the east side of the county from one to 100 acres; drainage is generally very judicious; work along with chalk, marl, or other heavy, loam, clay, and in some places even red soil. Some of the best of the soil is very common. Marls of Kibbly have been dug out to prepare potting loam, which marl is very well. The term for manure is loam, barrow, or cow-pie, some years. By being pressed the farmer can read them at his leisure.

5. *Implements.* Plough with two wheels, drawn by four or five horses, or six or eight oxen, in the strong lands, and two horses with a key to drive in the sandy soils. Various improved implements and working machines, some excellent mills on Lord Stafford's estates, driven by steam.

6. *Stocking.* Much practice, and still going on. Ploughing begins in early May in the south; it is a business which requires great energy and judgment, and has the most important operations as regards it in general, who in the first place get down to work, through some horses, but not to be used as much as the best of the stock in the weather. Many miles of hedges lately planted on the Stafford estates.

#### 7. *Arable Land.*

Following very badly down on the strong lands. Common crops of the county wheat, barley, oats, peas, and turnips. From about mid to mid till wheat grown on a heavy ground of sand, these crops are given to pigs and horses. Some hemp and flax are raised.

#### 8. *Grass.*

Some natural meadows on the farms and other rivers; and much attention paid to them. Artificial hedges and grasses grown on the sandy soils.

#### 9. *Gardens and Orchards.*

Many houses have small orchards, from whence they make little else for home consumption; and on the estates of Lord Stafford and Warrington the orchards are larger, and older in date for sale.

#### 10. *Woods and Plantations.*

A good deal of hedge-row timber, and some fine oak woods; also numerous young plantations. Harvested the timber and the situated hedge-row trees, but the broad-leaved timber character and less difficult on soil and situation. In this country few persons will buy their timber in any but the best and clearest which contributes much to its security.

#### 11. *Improvements.*

Black sand, and some irrigation. A good deal of draining done with brick, stone and flag stone. Some have drained in Stafford's estates. On the Llanelli estate of Lord Stafford (for 1891), in 1816 and 1817 there has been carried about 17,000 yards of embankment; 37,000 yards of water courses deepened and cleared; 46,000 yards of main drains made or

999

deepened; 315,000 yards of fence-ditches deepened, cleared, and established; 69,000 yards of old fences cleared; 50,000 yards of new ditch fences made; 51,000 yards of new draining; and 492,000 yards of water-ground drainage, laid with tiles and filled with stones; besides the number of many new farms of the most convenient plans and economical construction. But to have an adequate idea of these and other improvements effected by this establishment and various noblemen, it is necessary to pursue the very interesting work of Lord Stafford's

On the Williams estate of Lord Stafford (A. 1805), constant work has been done; so that several years, before becoming his in vision and during his vision, may now be represented in all things with care. The estate, as Lord Stafford, has then been added to many more to the estate. But the most considerable work done upon these estates is the drainage of the country by the Williams and various noblemen. It is necessary to pursue the very interesting work of Lord Stafford's

the direction of his progress, and its preservation heretofore is entirely owed to a survey done by his lordship.

These years consisted of an extensive tract, meeting with the land steadily circumstances, to over twelve hundred acres. The soil is composed of a black sand, known as a bed of red sand, full of water. They are bounded chiefly by the highest part of these estates, and represent the yards of the country, which also belongs to it, and which is composed of some of the best, sandy and better soil in the country. They had evidently found the bottom of an extensive lake. The drainage began the construction of many fields, and some through them. These fields are known to the country by the name of drains, being distinguished from each other by the name of the place from which or past which, they flow. These drains to the town (which river drains the whole of this country into the Severn) was devised and executed in the country to meet them the land through which they ran.

A full description of these works was completed by the means of a full description, who turned their hand in work there for a portion of the summer season only. During the rest of the year it was impossible to use them. They did not last a small quantity of sand, and were in some places as well as it

was at all times difficult to walk over them. It being necessary to select the best roads to take, they were cleared with water after almost every storm tide, owing to which the

drainage of the neighbourhood was subject to frequent interruption. The adjoining lands, however, so as to prevent any further water, were kept to nearly a state of

main, owing to there being no level by which they could be drained while the extensive district continued subject to such inundations.

The difficulty which occurred in draining the tract of land above from the west of level and from the river (Owen being pointed so high by the mill race as to drive the water back to great distances upon the land). The plan for draining this extensive district was extremely well considered and judiciously laid out, in the double view of securing the object and of interfering as little as possible with private property and the existing subterranean drainage on the 'Tern'. It was suggested by John Barker Esq. the first Commissioner under the Act. The great object was to gain as much additional level as would enable the water to be discharged into the river. This was to be obtained by beginning the cut which was to carry off the water, considerable way lower down the 'Tern' than the water had hitherto been discharged into that river, and good level below the mill-race at Long, which occurred this purpose. The original course of the stream was straightened and widened, but they were still made to convey the water from the uplands, and to discharge them into the Tern in their original direction. To prevent them overflowing the adjacent lands, and in order to prevent the water from the 'Tern' on the upper course, these banks were strengthened for the whole length of their course through the Widmore. These are technically called arpe-banks. At the head of these banks deep ditches were carried, but in a more direct line than

the course of the stream. Into these ditches the drainage of the uplands is carried. The level which was then brought from the river 'Tern' from below Long Mill was carried in a tunnel under the intervening area, and was continued below the several ditches in slight oblique, and thus communication with the ditches described as having been made below the basin which contained the waste of these levels.

To some distance it has been necessary to construct one set of culverts over another in order that the water coming from the uplands may be kept in the several basins through which they had commonly flowed, and that the water flowing from the uplands might not fall into the back ditches; it being again explained, that the water flowing from the higher grounds is still confined to the original stream or brooks on an upper level; the drainage water alone of the uplands being driven into the back ditches. Thus the great additional level has been obtained, and the whole of this district is now rapidly relieved of water, and such things as flood has not been known for years. This district is in some measure so cut, that the old course of the 'Tern' stream, which formerly conducted the water of that brook in one direction has with little difficulty been made part of the drainage, and to carry the drainage water in exactly the contrary direction, a new channel having been cut for the stream. Taking advantage of the drainage main ditches upon the upper system have been carried into all the neighbouring parts of the estate, thereby enabling the land and the tenant to construct various other improvements.

This district has been subsequently divided into regular squares by great ditches, which fall into the main ditch; and wherever it has been possible, these ditches have been made to serve this purpose, as well as that of a fence to the new roads which have been constructed across these moors. In one instance, one of these roads has been carried in a straight line for about two miles. On each side of this road trees have been planted, at regular distances, which will soon form one of the finest avenues in England. These moors have hitherto been all regularly under-tilled by turf drains, which were made very well. In the different ditches the water was discharged, to come back the water during the summer preserving the meadows in a state of perfect verdure. The water is let off at least once in every four or five days, and being carried off with so much velocity in parallel, it runs and keeps clear both the ditches and the under-tilled drains. The meadows of these moors are all divided into small squares, and have been greatly improved by very heavy and improved sowings and top-dressings; and their value as far as is

known, is every instance, is fully decided. With improvements like that a very large sum of money would be required beyond what was necessary owing to the insufficiency of the late surveyor belonging to the commission, which is not yet decided. The drainage however, has lately been under a surveyor (Lewke) approved of by Lord Stafford in terms of the Act and the expense is diminished, and the whole put in better state.

A very rapid improvement has taken place on these lands. In place of being the very worst part of the estate, they are rapidly becoming equal to the best and most fertile soil in it. In order to further show them the same which would be the water, from the 'Tern' stream, they have been improved with various improvements. A plan of the Widmore portion in 1810, and another subsequent to this improvement (1811), will serve to give an idea of the state of the land before and after the improvements. It is worthy the attention and inspection of an intelligent agriculturist and improver. (Lewke, p. 254.)

\_\_\_\_\_

lately introduced, it is grown, once in two or three years at least on small, and British with some sheep, since it is at Christmas the morning, this is to grow in a top-dressing. Youngling sheep and cattle for chief application of the grey lands, and some, drying and breaking down.

#### 6. Gardens and Orchards

Good market gardens and orchards about Northampton; all seasons articles grown there well, but various grapes, pines, and pine-apples to be had from London cheaper than they can be grown in the county.

#### 7. Woods and Plantations

Very extensive there are forests, oaks, yew, and woods, and plantations being finished property. Roushington forest the most considerable, nearly twenty miles in length, and covering 8 or 10,000 acres. Whitewood church estate and 700 acres, with 10,000 acres, making in all 20,000 acres the oaks and other classes are supposed to amount to 20,000 acres more, making in all 40,000 acres of woodland in the county. The forest lands are in general very respectably managed, the Crown has a right to the timber the Duke of Grafton and others in the neighbourhood, and the township to the pastures, the woods which are private and entire property are better managed.

#### 10. Live Stock

Cattle of the county, the long-headed breed, but various others introduced for the county and the dairy.

Sheep of various breeds; a good many are Leicester.

Stables of the strong black breed, best for the county, the grey or large waggon. Blood horses formerly bred, but less so, as the best blood horses come from outside.

Age, bred between the Rotherham and the Temple.

#### 11. Political Economy

Wool, but many handsome bright some small. Manufactures - cloth for the army and navy and various home use woolen stuffs, as muslins, calicoes, and even-lings. Several small textile factories for the purposes of agriculture, increasing chiefly of farmers. The Lanesport factory is one of those which was founded in 1767, some of the best land for purchasing lands on agriculture and domestic economy, and almost to a description of association very considerable. A great source of improvement would be the draining of the inferior grass lands, and the temporary laying down of the common, cropped tillage lands. Donaldson has drawn on able comparison between the improvement of trade in the County of Gwent, in Fife, and that of Northamptonshire, which shows how very far behind the latter county is in textile culture.

7804. YORKSHIRE, 3,638,350 acres divided into three Ridings, each of which is as extensive as the generality of other counties

7805. West Riding of Yorkshire, 1,568,000 acres of irregular country hilly and mountainous towards the north and more level on the east. It contains a great extent of surface well adapted for husbandry and is the seat of large and extensive manufactures. A survey of this Riding of singular utility and interest, and the printed copy, as contained in several gentlemen of the county will in future times be considered as a curious document, displaying as it does local opinions so different from those considered as liberal and enlightened. (Drover's West Riding 1790. Marshall's Review 1818. Smith's Geological Map 1821.)

#### 1. Geographical State and Circumstances

Climate, moderate and healthy, occupying on the low surface near the Ouse, runs at Sheffield about thirty three miles in the year.

Surface irregular, but the middle and modern parts nearly level, fertile lands generally covered with walls and hedges and grown from clay strong of it to iron.

Minerals. Coal, iron, iron ore, lead and some copper which have been wrought for years past.

Rivers. Ouse, Don, Golds, Aire, and Wharfe all considerable, besides others of less importance.

#### 2. Property

Irish divided, but some large estates, as those of the Duke of Northall, R. Fitzwilliam, R. Fitzwilliam, &c.

#### 3. Buildings

Waterside houses one of the largest and most magnificent in the kingdom. Then houses built, and badly situated as in most English counties Lord Fitzwilliam has erected considerable and expensive houses for his own use. Great waste of country for farm operations.

#### 4. Occupation

Various small, for one of 400 acres a dozen under fifty acres of 100 acres and great farms, few farms, the amount on one some would not increase they had become methodical country in general much plagued by attorney clerks, who would have business or make it.

#### 5. Implements

Rotherham though general over the whole district, but some have used and other improved implements as well as some ploughs, are wanting.

#### 6. Arable Land

Rural manufactures from grass part of the land held by manufacturers (but) farmers not well managed compared with Scotland, but tolerable compared with other districts of England. A grass will ripen on the eastern mountains at an elevation of 800 feet, but on the calcareous soils of the West Riding it ripens considerably higher and at 500 feet better than here at 800. Much in the district of limestone soil. Besides the usual crops, some flax, rape, liquorice, rhubarb, and wild cultivated. Some excellent nurseries on fells.

#### 7. Grass

Great part of the county under old pastures, but some new ones, chiefly applied to the feeding of horned cattle cattle

generally made for no grass, and finished by still feeding as turnips, sheep sometimes fed on turnips, by building. Grazing much better understood than elsewhere.

#### 8. Of ridges and Orchards

A particular species of pine grows at Rotherham and in the neighbourhood called the westerly. It grows well both upon stone and limestone, is hardy, a good bearer, and arrives upon any soil but does not bear so well as in the flower to grow, on any soil on limestone or gravel. On a strong deep soil, the trees run too much to wood, and do not bear fruit in proportion. These plants blossom better than any other sort, and are produced from seed. The first sale from 11s. per perch, which sound and good as far when cropped and damaged. They are easily hurt by rain. Plants are to be had from stout public nurseries, and in gardens they should be planted on a layer of lime or chalk.

Woods and Plantations. Much oak and ash wood grown, and a ready market found at the shipping and iron increasing towns.

#### 10. Waste Lands

Two hundred and sixty five thousand acres capable of cultivation.

#### 11. Improvements

Warp is the most remarkable only described by Lord Harris, and Day of Doncaster.

#### 12. Live Stock

A great variety of breeds of cattle and sheep in use but no one generally preferred. Some Leas, which milk earlier of the year, the cup full of olive milk, and give more milk of milk, which entirely removes the flavor. These generally used in drought not many breed on p in the eastern part of the district, but in use among the farmers a small dairy race.

#### 13. Political Economy

Many good and many bad roads, various canals. Numerous manufactures of all sorts, calicoes, muslins, and every branch of woolen goods. At Sheffield every kind of cutlery, arms, chains, guns at Rotherham, iron works. There are other manufactures the cause of the wealth of the West Riding.

#### 14. Means of Improvement

Division of common, melioration of wastes, better relations, &c.

7806. NORTH RIDING OF YORKSHIRE, 1,511,187 acres of bold hilly country with some fertile valleys and extensive moor lands, chiefly remarkable for breeding horses, and especially the sort known as Cleveland bays. (Tuke's Report, 1789. Marshall's Review 1808. Smith's Geological Map 1821.)

#### 1. Geographical State and Circumstances

Climate dry like that of other districts bordering on the German Ocean. Cold and windy during the first half of the year. Milder in June, when west winds begin to prevail, vegetation and vegetation to June.

Soil and surface on the coast, clay, and British soil on almost every side upon transition soil in some places west of Whitby a deep rich soil of Cleveland, fertile chalk, and some free hilly, soil of York generally a rich soil.

Minerals. Handmade tiles of low in the hills of iron ore and limestone, and the only stone which in the mind not used on them; purple being found in the same manner, which was formerly quarried from them, but is not required. Great deal of coal, and pyrites are equally abundant in the coal at Newcastle, the construction of the ship was transferred to the latter place. There are coal and pyrites in the same but not much worked. Also copper lead, ironstone, slate, marble, marl, &c. little worked or abandoned.

#### 2. Property

One third of the Riding possessed by proprietary part of owners from 2000 to 10,000 per annum. Many gentlemen's estates and the proprietors made most part of the year in town; tenants mostly English.

#### 3. Buildings

Manors and farm houses, as in the West Riding, but rather inferior cottages frequently inferior small and very

scarcely with two young dams and two-thirds horse. Close watercourse lands used as at the poorer parts of Scotland, which are sources of insects and infection, and very way unsalubrious.

#### 4. Occupation

Farms on the whole small, very very small. Farmers often, improvers, and others smaller than have been established, and cultivate their children. Few leases.

#### 5. Implements

Rotherham or Dutch plough, but except for Rotherham has been used with horse and a single pair of oxen. In 1808, in use, Rotherham almost wholly of Rotherham and to be driven by two, two or three horses, almost all. Whole industry of work, to be in the county the district have a better one, but not the others. Another variety the harvest work (see 1808).

#### 6. Arable Land

In the whole of York one third in tillage about Cleveland one half, on the western much less. Culture and rotation in the West Riding. Ryegrass frequently more than wheat in the light sandy soil, often mixed with wheat, and then called Marston.

Wheat much cultivated. Five years prior to 1789 in the whole of York and Rotherham. In the latter district it is still not under the notice of royal authority, and was kept well cultivated by men who had formerly been employed about the tobacco plantations in America who not only used a poor

#### 4. Discussion

**4. Occupations.**  
Farms generally large in the north, some from 200 to 400  
in size; in various parts from 50 to 150 and from 100 to  
2000 acres. The capital necessary

[illegible]

## 6. Implementation

5. *Implement*  
Of the most approved kind; and some of these, as the plough, drill, horse-hoe, &c. owe their chief merits to the improvements of Bailey. A pair of pruning shears recommended as preferable to those in common use for cutting hedges. They consist of a strong sharp knife, six inches long, moving backward two square-edged cheeks, the upper handle is two feet six inches long, and the other by feet three inches. (See *Encyclopædia of Gardening* 2nd ed. 1754. Art. 125.)

**6. Enclosures.**

7. Available for sale

7 *Arable Land.*  
Trench ploughing practised by a few in breaking up grass lands. About 1790, when horses were scarce and cost a good many guineas were used for ploughing and carting about the farm. But after a few years' trial, they were given up; the were harnessed both with yokes and collars, and only ploughed half day at time.

Following on all soils once in three or four years, was general through the county till the introduction of turnips. On soils improper for this root the naked fallow still prevails, but the quantity of fallow probably on all soils will after long series of good culture, become less necessary and may in many cases be finally dispensed with.

They were first grown in the northern part of the county about 1723. Professor Oke, the proprietor of Koch, brought Andrew Wiley or Anderson to cultivate tobacco at Koch, for the purpose of fueling cattle that Wiley afterwards settled at Lumbury garden and was employed for many years to sow tobacco for all the neighborhood, and his business this way was great. He was hired to ride and sow that his master

During the war, the *Wichita Eagle* was introduced as the same breed and as first prize. The *Wichita Eagle* was introduced as the same breed and as first prize. The *Wichita Eagle* was introduced as the same breed and as first prize.

The broadest culture of turnips, on the northern parts of the county was not inferior to any we ever saw and in respect accurate, regular clean looking, superior to what we ever observed in Norfolk Suffolk or other similar districts which we have examined.

Drilling barrels was first introduced to the county about 1780. Drilling bits, as well as other crops evidently originated with Tall, whose first work, *Barrenness of Work on Horse Acres*, was published in 1781. It appears that Orie-

**7510 CUMBERLAND** 570,940 acres of mountainous district, remarkable for its picturesque beauty and also of late greatly improved in its agriculture. The mountains of the late Northrop class of about 1800 ft. are the highest in the State. The townships of the county are 10, and of J. C. Curwen, Esq., in field culture, have obtained one of the best crops of the county, which, for the soil and climate permit, may be considered as on a par with Northumberland. *Pringle's Gazetteer of Vermont*, 1844. *General View by J. Bailey and G. Colby, 1854. Mearns's Review, 1868. Smith's Geographical Map, 1894.*

## 1. Introduction

[illegible]

Arbitrarily, in Pennsylvania, began to drill machine about 1766; and next we find Philip Barstow of Conry drilling in 1780; and Friggle drilling "from stone below from a mill's back" in

1734 or 1737. William Deane, who was well acquainted with the history of the English having been a prisoner of war sent to need in those districts for six or seven years, when, after his return, his cultivation was pursued, with an intention was only of the most modest, seeking but to make himself master of the natural operations, and all artificiality was excluded. The produce was considered of the same value as that of France, and the same price was given for it. The soil was not so fertile as in Norfolk or elsewhere and in 1762, when he returned to Westbury, near Exeter in Dorsetshire, his intention was to have adopted his principles upon a large scale to the advantage of the country. He was very desirous of a large weight of produce, and he lowered the quantity, yet, he succeeded in obtaining an equal or more than the former yield the same quantity that it was immediately followed, not only by several farmers, but his vicinity had been shown very farmers adjoining Finglo, whose crops they had seen, and they were very desirous to have a specimen to their own use. In 1767, you have a specimen of the same.

**8. Growth**

8 Grass  
Not much old grass in the county

Cattle the short-horned, long horned, Devonshire, and wild cattle.  
Sheep the Cheviot, black, and long-wooled. The smaller

lines of breeding were introduced into the county by one of the  
Bakewell's fine distaffs, Colley of South Durham, and since then  
the best wools in the world have been raised in this county.  
The high value of the wools has been the principal cause  
of excitation, and sacred allusion to the rule of breeding  
breeding within the canonical degree of refinement, but there  
is no such thing as a royal warrant, and the wools are  
not the principal farmers of this district are now the principal  
pasture the most scientific, however in the kingdom, who have  
pursued it with an ardour and unwearied attention that have

not fail of success.

However far draughts have, let from Clarendale

Goats are kept in small numbers on many parts of the Cheroke hills, not so much as an object of trade, but the shepherd asserts that the sheep flock is healthier where a few goats are pastured. This probably may be the case, as it is well known that goats eat some plants with impunity that are deadly poisons to other kinds of domestic animals. The chief goat trade made of sheep goats is from their milk being sold to merchants, who come in to winter on the winter season.

12. Political Economy

**12. Political Economy.**  
Kinds of wheat or limestone, and vitally good. Manufactures, gloves at Hetham, plant straw for cottagers and lacework hats, and also for the three of the higher classes. Woolens in five places; and variety of work connected with the commerce and industry of the West of England. No agriculture, but the valley below in little distance, but thinks if public provision were made in each county and supported by a rate on the income of its proprietors that would be the most effective means of promoting agricultural improvement.

innuous district, remarkable for its picturesque beauty. The exertions of the late Bishop of Llandaff in plant-contributed much to the improvement of this county considered as on a par with Northumberland. *Pres-Binley and G Colley, 1804. Marriot's Review, 1806*

with steel, and the witness thought, in addition, to cut out the entire center of the iron.

3. Improvements  
Drinking and irrigation, not much promised. The Rev M Frazee, of Dickinson, Minnesota, communicated to Vincennes a note describing a water pump a mile and without the expense of stone, and it possibly will be 25 miles from the source of country there presently or later. The water, with the power in overflows, flows by gutter into a basin, suspended beyond the bank, which when full, by means of a lever raises a plug at the bottom of the pond. After that, the hot being only, it becomes empty, and when the pond is nearly empty the plug is raised to its place. If the plug were placed nearer the source of water, it would be in the ground once he started, and would be on the spot.

[illegible]

They were generally perverted in learning and aiming. The various national groups were characterized as follows:—The prominent ones were of Italian and German origin. The latter were the most numerous, but of inferior talent. They were generally of the lower middle class, and were not very intelligent. They were generally of the lower middle class, and were not very intelligent. They were generally of the lower middle class, and were not very intelligent.

The following North Devon cow, when fattened to its fullest weight, averaged eight score per quarter; and the ordinary average of its age, at five years old, and equally well finished, must be judged higher than about seven score per quarter above the weight of its fattened neighbor.

The most graphic in this aspect, is to sell the corn, at four or five years old, to the grinders in the county of Beaumont, who feed them, for a supply in the South, Bristol, and London markets. Very few in the proportion raised can get in the market, which may in a great measure be ascribed to the great inferior quality of the corn, and to the failure of some food for the whole supply; and for which, indeed, a political reason may be drawn, from the deplorable wet season in which the lands are

In South Down we find a mixture of the North Down with a larger amount of the same line, called the Old Man of Down. This variety is said to have originated from the blood of a wild boar, which was introduced into the country by the Duke of Devon, in 1660, and he is said to have been a very heavy, an excellent hunter and of the pure, heavy kind, resembling the type, but of an early date in the country here prevalent in the greatest North Down blood. A man who has been in, however, much interested, as it produces a greater variety to prove in a shorter time than is experienced in the North Down stock, which is all on account of the mixture of blood, and produces a greater variety in color, and is very profitable to the farmer.

State, the Emperor hawk, a hunted animal, with a modern-day eagle of war, which has been, and being the most magnificent bird from the country into Persia, was used by the chieftains of North and South India, Cochin, Ceylon, Persia, Thibet, and other places in the country.

[illegible]

The Merioneth, Rylance, Down, and other valuable breeds have been tried by numerous but I am sure they than any other native country. Native breed of sheep large, and long-legged.

There is a small compact breed, with the exception of the farm-houses in Ireland, these in Devonshire have perhaps as hard a measure of superior and ill-used, sent out to them, as any where to be met with in the United Kingdom.

## 11 Political Economy

Had the roads of this country been laid out in the judicious manner practiced by the Indians of North America, the men would have been found to follow the water courses in all cases where they might lead in their general direction, towards the point assigned for carrying them. In doing this, Indians

such judgment would have been displaced and its grasp based secured to posterity than in that which has been adopted by the original projectors of some of the most important and most beautiful works in the country. This is clearly the

measured by the road between Barnstable and Chatham which, instead of being conducted through the valley of the Taw, is carried over the highest bows of the river hills, where the traveler is unconsciously compelled to ascend and descend the steepest hills in the country. The same may be said of the

wood between Hissland and Torrington by the great timber hills, one of the best being carried along the foot of the river hills, and through the valley of the Torridge river.

*Mammals* of various sorts were formerly common here but are at present on the decline many mammals, birds and wilds consisting numerous birds at 12 months 2 years

postponed, postponement; and thus hindrance there to arrive

When Vancouver is at present we do not know; we hope he may long live to witness the extension of education which is not only in this, but in almost every country

in the world; and we hope all those whom he delegates personally who may ever be sent to visit the shores of the Pacific, to see the progress of civilization, by knowledge and good conduct, against the degradation consequent upon ignorance and vice.

**798. CORNWALL.** A peninsular hilly surface, of 788,684 acres, remarkable for its salubrity, and of late greatly improved in its agriculture, the object of which is chiefly corn. It is the country of Sir H. Dey who may be considered as having eminently contributed to agricultural science by his agricultural chemistry. The inhabitants have been remarkable from the time of the Romans for their mildness and complexity of temper: urbanity, hospitality, courteousness, and liberality. (*Fraser's Cornwall*, 1794. *Weymouth's Cornwall*, 1810. *Morrell's Review* 1817. *Edin. Gen. Abstract*, 1860.)

#### 1. Geographical State and Circumstances

Cornwall, the best of other peninsular situations lying due to the south and west, is bounded on the north and east, and more so to the west and south. Plains, shrubs, and even the most fertile soils on the sea-coast, receive much injury from the violence of the westerly wind, and the only remedy of this evil, which it derives with great force before it, is the planting of wheat and corn. The plants have been totally destroyed. After a storm, the plants have their roots much torn, and their leaves corroded and discoloured as if scorched and taste of a pungent saltness. Trees and shrubs shrivel and lean away to the westward, and appear as if clipped by the gale's breath. The only shrub which seems to bear the sea air is the manzanilla.

Soils remarkably various; moor and granite follow in rapid succession, some hills very steep. The soil is generally clay and heavy, mixed in a manner that renders it almost impossible to delineate the boundaries and extent of each.

Minerals chiefly tin and copper. For the former Cornwall has been famous from the remotest antiquity as some think, from the days of the Phoenicians.

#### 2. Property.

Very much divided, subdivided, and ventuously intermixed. Ranges from twenty acres to 100 acres, very few exceeding 400 per annum. Many gentlemen and noblemen in this county occupy their own estates and glades, and keep their grounds in a very superior state of cultivation. The management of great estates is generally given to strangers.

Political relations. It is to be hoped that I had been a native of Cornwall, from this kind of description. It would not have been worthy of notice, but in my situation through the country I have met with fellow sufferers, not with whom who can think to become so. As such cases have occurred and may occur again, it behoves every man who is about to occupy a farm for years, to make enquiry whether it be an unfettered estate or not. In some the possessor having the power of letting for his own life only or else of his death, the occupier is left entirely at the mercy of his successor. (*Weymouth's Cornwall*, 1810.)

#### 3. Buildings.

Old farm-houses of mud and daub, the lower divisions consist of kitchen, and an apartment supplied with the seats of parlour but called (improperly) the higher side, cellar and dairy room but these latter are frequently under the roof of the house very low not cooled, and two bad-chambers over the floor of the chamber are of oak plank the ground-floor earth, lime-stone, or flagstone.

The farm-offices, built of the same materials, consisting of barn, cow and ox sheds and huts, stand in confusion about the dwelling. The intervening and circumjacent ground is called the farmer's town place. As to that essential appendage, a regular farm-yard, it is a convenience not often met with in any part of the county.

Some good new farmhouses erected entirely on newly enclosed lands. One for forty-six acres has very neat elevation (fig. 1116.), and the plan (fig. 1117) contains a feeding place into which the cattle are carried (the cart being backed into it), and from whence the sheep and cows are fed (c) place for pigs of corn (d) either for milking or winter-feeding, the man is tied to posts (e) there are troughs for turneps (f) wells, or wells for hay or straw (g) lean-to, for sheep (h) lanes, in which half-acre sheep are kept in farms, the number

being completed again soon as any are sold (g) a stable house, used as a barn (h) open shed for cattle (i) hanging down with

1116

built inside, and through which the fodder is brought to supply

1117

the cattle, and in time kept always dry (h) a door and staircase leading up to the wood chamber (i) The steps rise much as to be quite out of the way of the ox feeding in that side of the house.

College. "I had occasion often, in my country walks during my vacancy, to take shelter in some of these comfortable dwellings, and found the poor inhabitants busy in picking their towels, brooms, and mats, to catch the water pouring in at the roof. However the momentous business generally has that great source of comfort, a garden, attached to it. These very comfortable places of refuge, by Captain Panton of Brixton are described by the surveyor.

#### 4. Occupation.

Farms from three or four to three or four hundred acres, mostly from 200 to 300 a year. Leases on well-cultivated farms generally from fourteen to twenty-one years.

#### 5. Implements.

No country affords a greater variety of wheel and other carriages. The harvest waggons (fig. 1118) have beds before and

1118

behind, and is open in the middle, it carries about 300 sheaves of corn. When drawn by horses, shafts are applied; when by oxen, poles. An arch of beams over the hind wheels prevents the corn from falling on shoes.

The axle is another light wheel carrying for carrying corn

and hay. It consists of a light, open, long body, drawn open two wheels, a tail wheel over the whole, preventing the bed from heaving upon them; it will carry about 200 or 300 sheaves which are secured by ropes, at hooking to poles or ladders.

A design for corn, hay carriages (fig. 1119. c) a side view (g)

1119

Self and an infant. About Merthyr, however, are not only healthy but an infant. They are considered as the best of all soil, superior even to any.

**Livestock.** Great deal cultivated, and found productive. There is a strong opinion that the most could not find that the *Merthyr* is the best, and the most productive, and the most abundant crops. A species of *Cypripedium* (which *Merthyr* is said to be) and the *Merthyr* is the best and the most abundant crops.

#### 7. Grass Lands.

Of very limited extent, but sometimes very productive.

#### 8. Cattle and Cattle.

Very productive, and in general carefully attended to. Cattle of the *Merthyr* are of great value, and with proper care, the *Merthyr* is the best, and the most productive, and the most abundant crops.

**Cattle.** Generally attended to all farms. Many other to such extent, and produce of great value. Many of the *Merthyr* are of great value, and with proper care, the *Merthyr* is the best, and the most productive, and the most abundant crops.

#### 9. Woods and Plantations.

Very limited extent, and the woods are of great value. Many of the *Merthyr* are of great value, and with proper care, the *Merthyr* is the best, and the most productive, and the most abundant crops.

#### 10. Improvements.

No persons are known to have any of the *Merthyr* improved. The *Merthyr* is the best, and the most productive, and the most abundant crops.

#### 11. The Stock.

**Merthyr cattle** well known. Though there can be no doubt that the *Merthyr* is the best, and the most productive, and the most abundant crops. The *Merthyr* is the best, and the most productive, and the most abundant crops.

T. The *Merthyr* is the best, and the most productive, and the most abundant crops. The *Merthyr* is the best, and the most productive, and the most abundant crops.

**688. Gwynedd.** A rocky hilly surface, of which 8000 acres are under cultivation. The climate rather warmer than that of Jersey and the soil generally light, on granite, gneiss, or schist. The operative classes resemble those of England more than those of Jersey.

**Agony.** The *Merthyr* is the best, and the most productive, and the most abundant crops. The *Merthyr* is the best, and the most productive, and the most abundant crops.

As to the question of superiority between the cattle of other islands, it is not worth the trouble of the *Merthyr* is the best, and the most productive, and the most abundant crops.

There is a strong opinion that the most could not find that the *Merthyr* is the best, and the most productive, and the most abundant crops.

The *Merthyr* is the best, and the most productive, and the most abundant crops. The *Merthyr* is the best, and the most productive, and the most abundant crops.

### SECT. II. Agricultural Survey of Wales.

**7629. A hilly mountainous surface of 5,200,000 acres, with a climate colder than that of England, and more moist in the proportion of thirty four, the average number of the inches of rain which falls in Wales, to twenty-two, the number for England. The soil is generally of an inferior description, and the great proportion of mountainous surface is fit only for pasturage and planting. Little attention was given to cultivation till the middle of the eighteenth century. From that time the present agriculture has been gradually improving. A general view of it, as in 1833, has been published by the Rev W Davis of Montgomeryshire, whose work we shall adopt as our guide.**

**7630. NORTH WALES.** 1,574,510 acres, chiefly of mountainous surface, in six counties, including the Isle of Anglesea. The climate humid and cold in elevated situations, but warmer in the valleys and near the sea. The soil moory, coarse, clayey, and otherwise unfavourable in most places, excepting in the valleys on the banks of streams. Minerals chiefly copper, lead and iron. The famous *Merthyr* and *Ferry* mines in Anglesea have been worked since 1708. Lead is chiefly worked in Flintshire. Excellent slate

were would have completed the whole, as the materials were already coming on the spot. On the 24th of January, 1796, an extremely high tide raised twenty rods of water in the beach, in which state it now lies. The bank was made of three layers, covered with double-siding, covered with mud, then with stone, and on the outside with a good covering of stones, between deep at the top, and decreasing to three inches at the bottom. It was fifty-one yards wide at the base, four yards at the summit, and five yards high; the slope of the outside to that of the land-side is seven to four.

The embankment and improvement of Fresh-Hewer and Fresh-Hewer sands, between Connermore and Manod, have been above 170 years in contemplation, and never yet performed. In 1709 the John Wynn, of Gwydir, intended to have brought over Sir Hugh Myddelton, the only landed gentleman to undertake the work; but as Myddelton was wanted away and paper for the year 1710, some Dutch engineers were proposed to the project, but to no effect. In 1770, Sir John John Lloyd, Bart. who was always active in works of public utility, and others, brought the subject before the committee, at the same time proposing a narrow road from London to Dublin, across the Fresh-Hewer sands, where embankment, drainage, the embankment, was sent

down by the Duke of Argyll, and two estimates were made. The late Mr. Wynn's plan was probably correct in principle, but the land given in that to be given subsequent to the payment of 20,000*l.* and upwards, when the whole scheme was abandoned by the same spirit and considerations of some neighbouring proprietors.

In 1820, W. A. Madocks, Esq. M.P., having a considerable estate on the Connermore side, and having there an excellent quarry of stone, he proposed to build a road and to build the village of Fresh-Hewer (or, by carrying out from both shores an intention built of every modern completed and led to that their own shore by the washing of the sea. The two banks were washed and then a bridge of stone built in the middle, but owing to the force of the tide, and the enormous weight of the very exposed structure it was not completed before he was ruined. The project, however, this scheme; and the proprietor who had settled in the neighbourhood, and in 1824, was lived long enough to see realized by others all that he had anticipated, and for which he had sacrificed a very considerable fortune.

1134

The River Dee Company, established by Act of Parliament in 1760, by several gentlemen made in the years 1764, 1765, 1766, and 1770, on the river Dee, in Flintshire, to keep out the tide and land-floods, they have been enabled to gain 2100 acres, which are now covered with good crops of corn of 1000*l.* and of artificial grasses, and the whole submitted to be incorporated into a township, bearing the very appropriate name of Goddard.

In various parts of the coast of Anglesea, and the other maritime counties of North Wales, there is still much to be done by embanking. Connermore has been entirely reclaimed in the acquisition of W. A. Madocks giving its land for improvement. Indeed his improvements are of such magnitude and variety designed with such taste, and executed with such facility that a witness report of them would appear if those who have not personally visited the place, were like the people of romance. (See the narrative of former descriptions. In harbours, embankments, roads, buildings, waste plantations, and rural and commercial improvements in general, nothing but that a Tremadoc Church plantation can be just to the reader.

#### 10. Live Stock.

Cattle and horses are the staple exports of Anglesea. When numerous herds are brought in the island for the English market, they are compelled to return to driven across the strait of the Menai, and although numbers of the weather are sometimes swept down by the force of the current for some miles, yet losses seldom or never happen. A chain bridge has been between across this strait.

The characteristics of a choice Anglesea ox, when grown in great plenty with those of a Roman one, as described by Cato, are: excellent colour, with white eyes; a remarkably broad side; high and wide deep chest; long deep body; and short and long horns, turning upwards. Such well thought, that in some points they were nearer to that of

perfection in shape, than any other he ever saw; his own improved breed, escaped. Some farmers suppose it is a good stock, by having their hawthorn put under their trees, their horns become of yellowish colour longer and finer than common and, upon the whole, possess the greatest idea of symmetry.

The average weight of their quarters, when fat, at three or four years old, is from eight to eleven stone pounds.

The proprietors of Llana and Llanfyllid, in Connermore, having the same kind of unsifted surface, though not all together so good, as at Anglesea, has therefore a breed of cattle similar to several of their characteristics.

The cattle in the remaining part of Connermore, and in the whole of the county of Merioneth, some few other places excepted, seem to be descendants of the above breed of a high size, large, and strong, having nothing to recommend them save their extreme hardness, and consequently cheapness of purchase. The blackheads of the counties of Denbigh and Montgomery shared with the same party men. In the whole, and in the county of Flint, the cattle are of a superior kind, larger, and of all varieties of colour. The natives of the mountain from Anglesea to Holywell, and thence along the sea towards Llanfyllid, are included very quick fenders.

Neither good horses nor sheep are made in North Wales by ordinary farmers.

Sheep. The largest of the native breeds is that of Anglesea; they have white legs and faces, and are generally without horns.

The second kind of sheep in North Wales is that of the mountain. They have, generally, white faces and legs; some have horns, and others none. The number and of their weight than were to nine years of age, and the wool from three quarters of a stone to one stone and a half.

The third kind is peculiar to the Llana side in Connermore; it is a small breed, the only one of the kind which produces greater wool than of every other Welsh

leaf of brilliant yellow. In the south of Pennsylvania, on the Ohio & Potomac, the flowers are of a very deep yellow and sometimes almost scarlet, while the leaves are - as in the above - brown above and very pale beneath. The vulgar is the common one.

## 2. Design

Fisheries of all kinds; two herrings, three of 1600 each, each pound net from thirty to one hundred acres; averages of Chesapeake between fish and shad runs. In the western portion of lake is the main crop, without impeding the conduct of the fishery; whilst they find convenience, though without profit, in a canoe and spruce-log stigs. In the lowlands, or main lake, especially in the more broad channels of the western portion, gleaning is considered, and generally recommended, as the most profitable.

Upon an average of the whole, the districts may be said to be occupied in that kind of system called mixed husbandry breeding, dairying, and tillage, varying in the proportion of each in different places, according to the imperiousness of existing circumstances, which will be hereafter more fully considered.

Formerly may be claimed as proprietors forming part of their own estates, small proprietors or yeomen, farmers of the old school, and last of all

[illegible]

**S. J. J. J.**

The *Wickham* plough is in common use, and perhaps a more awkward, cumbersome and is not so found in an awkward country as it is not maintained so out a furrow that to turn it open to water does. The share is like a large wedge that is counter down below the point of the share, underneath the counter. The earth below a thing moving, the counter is brought up, but a stick (a handle) very close to it is brought from the right side of the head of the share, and outside to the head part of the plough, thus is intended to turn the furrow which is sometimes awkward, and sometimes not as that this machine looks as if it drove of water.

[illegible]

Mr Lewis, M.P., of Gwent & Gog near Caermarthen, being equally unsuccessful in effecting a revolution at once, tried the plan of altering the old ploughs in slight degrees, and hopes, by one alteration after another, at length to transform them into the American form.

[illegible]

A key rule, with the head forming unequal angles with the handles, is in use in *clammers*, the only advantage of which is said to be that of not obliging the taker to stop in front backward at every catch.

### 4. *Strawberries*

In general, however, the situation is as follows. The important progress to date, namely, the improved delivery of social services, is better than anticipated by most observers. The country has been able to maintain a relatively high level of social services, which have benefited the Soviet Union, but at almost any price, and slowly decreasing. A few studies in industry will be conducted, but they will not be enough to maintain output in every branch of the economy.

Concerning the economy, the situation is as follows. The economy is growing, but not without difficulties, as many of the people who have come into the country from the Soviet Union are not yet fully integrated into the economy. The country is still a developing country, and the economy and society have not been completely integrated. The country is still a developing country, and the economy and society have not been completely integrated. The country is still a developing country, and the economy and society have not been completely integrated.

of a different condition, and therefore under the pressure of doing it, and, possibly, a little more in haste than the others. Thus, the members of the Society, in consequence of their work, would have a much superior claim to attention by the president of the same school, than the students who are

[illegible]

**E. Özmen**

By contrast some of the rivers of a district, with a mile of their fall in a given number of furlongs or miles, and of the numerous even which they flow and green distinguished by kinds of "quality" water, a geologist might give a fair estimate of the quality of the soils and growth of the respective valleys. Inevitably that district, though somewhat frequently traversed by water as well as by a railroad line.

[illegible]

The late Thomas Johnson, Esq., of Hildes, observes, "Fogging is getting out of repute. It must have originated in chance, and went of a momentary work of evil."

Clover is grown in some few places for seed, which is sown about three to four inches in common corn soil, the upper mill-stone being replaced for here with a square piece of oak furnished with eight wings studded with nails on their upper surfaces. These spikes, by their rapid motion, soon beat out the seed.

## 8 Cards

On the maritime coast of South Wales generally very productive, those of the cottagers better attended to than in other parts of the district. a pleasing mixture of flowers, small trees

Orchards in Radnashiro and Buzknochshiro thrive well in the valleys, but more especially in the vales of Wya and Ush

Not much older mode, except on 1

<sup>22</sup> It appears from old deeds, that estates were formerly sold at an inflated price, in consequence of their being crowded

There are a great many oak woods and copices in hills parts of the district, and many thriving plantations in every part of it. It is calculated that at an average six millions of trees are annually planted. If this be the fact, it is probable nine tenths of these either die or are doomed to prove so nothing for at this rate, in fifty years, there would be 150 times for every acre in South Wales, which, added to the old wood and copice would give 800 times, or enough to render the country once more

**Use foreign.**

**5. Improvements.**  
Numerous enclosures have been made, and fencing, draining and in some cases, watering provided in other countries. There are nearly 15,000 acres of fen and meads on the coast of Cardiganshire, which are considered highly improvable, and which is has been at different times in contemplation to embank. Of one of the worst parts of this land, the late agriculturalist Sir Anderson, who was struck with Johnes of Ebbw Vale, said that he never wheat in five years.

**D. Live Stock.**  
From ancient records it appears that the owners of Welsh cattle were white, with red ears, like the wild breed at Cheltenham (1894). They seemed to have been in wild state

have as the the

tends the coal-beds of Pennine shales the brownish black, or dark brown, of Glamorgan the black reefs of Cardiganshire, Carmarthenshire, and the western parts of the counties of Brecon and Radnor; introduced from Harwardale and Sharncliffe, into the moors and more fertile parts of

Cows are kept for breeding, and making butter and skim milk cream. John has proved, that at Haled cheese may be made at will so nearly resembling Parmesan, Swiss, Gloucester, or Cheshire that the difference cannot be perceived by good judges, and that the whole dairy stock in various

The sheep of South Wales are of four kinds: mountainous, Glamorgan vale sheep, Glamorgan Down sheep, and green and mottled breeds.

The *Glossaryx velle* sheep is the only breed in Wales, not introduced within memory of man, that produces wooling wool.

The Glenrhyon Down sheep is a beautiful and sometimes small breed. Feeding upon the clean and greenest pastures of the limestone tract, their wool is superior in quality to that of all other breeds. Their wool is of the short shaggy kind, and their cry is very peculiarly marked.

With several and advanced cases many experiments have been tried within the district, and most of them conducted without the expected success. Particular benefit of them have been observed in the case of the following diseases, which continue in their continuation whenever they are removed. The treatment must not be continued in the hospital for those within the district, but over those the reported modern hospitals have treated with the same, the best one, the greatest, against, and a long time.

area, in Galloway, by the London district. In use as the soil is so good, the farmer and the tenant have been able to produce a large quantity of butter, cheese, and other dairy produce, and the district is now a large producer of these articles. The district is also a large producer of other articles, such as wool, and other articles, and the district is now a large producer of these articles. The district is also a large producer of other articles, such as wool, and other articles, and the district is now a large producer of these articles.

**4. Improvements.**  
As a specimen, we will give some notion of what has been done on the estate of Mount Vernon, by General Darnley. The estate of Mount Vernon is situated in 1850 acres. The estate began the improvements in 1850, and since then, the estate has been improved in many ways. The estate has been improved in many ways, such as the construction of a new house, and the construction of a new house, and the construction of a new house. The estate has been improved in many ways, such as the construction of a new house, and the construction of a new house, and the construction of a new house.

**7640 KIRCUDDRISHIRE, 561,681 acres, and WIGTONSHIRE 288,950 acres (Ed. Gen. Sir 1855).** possessing great similarity of agricultural character have been included in one report, as the district of Galloway. The climate moist but rather warm in some parts of Wigtonshire, in general seasons, the crops on the open garden walls. The soil and surface of Galloway is exceedingly various. Almost the whole of Wigtonshire is very little elevated above the surface of the sea, but great part of Kircuddrishire is hilly and mountainous. The better soils are for the most part light, and of this and heavy loam there is a considerable portion in Wigtonshire. In some places in Kircuddrishire it is clayey or alluvial, and there is a great deal of peat-moss, and bog, as well as improved, or grass-bearing peat. The rocks of the county are argillaceous, granite, or whinstone with some freestone. Some mineral veins have been found, and one of lead, near Gate House of Fleet, was worked at the expense of the country for the work for some time, but without success. In an agricultural point of view, Galloway is chiefly remarkable for the breed of cattle. Gladstone, a millwright, who has invented a reaping machine, and prepared some improvements on the threshing machine and other implements, is of this district. (Smith's General View 1810.)

**1. Property.**  
More divided than in most of the counties of Scotland, the estate of Mount Vernon, by General Darnley, is situated in 1850 acres. The estate began the improvements in 1850, and since then, the estate has been improved in many ways. The estate has been improved in many ways, such as the construction of a new house, and the construction of a new house, and the construction of a new house.

**2. Occupation.**  
In the survey, where breeding cattle and sheep is the object, the estate of Mount Vernon, by General Darnley, is situated in 1850 acres. The estate began the improvements in 1850, and since then, the estate has been improved in many ways. The estate has been improved in many ways, such as the construction of a new house, and the construction of a new house, and the construction of a new house.

**3. Stocking.**  
Galloway district (1850) very generally in use, some small tracts on the vicinity of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway.

**4. Arable Land.**  
The statistics of the eighteenth century show that the district of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway.

**5. Remarks.**  
The statistics of the eighteenth century show that the district of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway.

the whole of the statistics of the eighteenth century show that the district of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway, and the district of Galloway.

**6. Weekly Reports.**  
In carrying on the improvements which have been mentioned, at a considerable distance from any general tradition, the estate of Mount Vernon, by General Darnley, is situated in 1850 acres. The estate began the improvements in 1850, and since then, the estate has been improved in many ways.

**7. Political Economy.**  
Improving roads, and some canals and railways, have been mentioned, at a considerable distance from any general tradition, the estate of Mount Vernon, by General Darnley, is situated in 1850 acres. The estate began the improvements in 1850, and since then, the estate has been improved in many ways.

**8. Woods and Plantations.**  
Of a very limited extent, but rapidly increasing. The estate of Mount Vernon, by General Darnley, is situated in 1850 acres. The estate began the improvements in 1850, and since then, the estate has been improved in many ways.

**9. Live Stock.**  
The Galloway breed of cattle is well known. The breed is, in general, indigenous, the management of cattle is well known, and the breed is, in general, indigenous, the management of cattle is well known, and the breed is, in general, indigenous.

1. The first step in the process is to identify the problem. This involves gathering information about the situation and understanding the needs of the stakeholders involved.

[illegible]

7016. KILDAIRIE. 200,000 acres, four fifths arable, woodland and pasture, and the rest bog. (Zarouan's Survey of Kildare, 1817. See Encyc. Brit.)

Parts of the *Boys of Africa* and other similar songs, contrary to the opinion of the women who of this country. The method is followed by a number of small boys and gentle school-boys but the most part is in the first twenty years of age, and when viewed from the distance, the effect is a picture of a school of monkeys. The Church of Khilano, or the church of the Holy Spirit, has been long renowned for the number of its converts and the strength of its pastors. But the old superstitions are still so strong, that the converts are not a true picture of the church, if the statement be correct. It is very unfortunate, consequently, as they will prevent every generous and sincere of it, it is constantly threatened of extinction. There is a new and a very interesting mission station, the Mission of the Holy Spirit, which is situated on a hill, overlooking the city of Khilano, and several villages, according to Wikhamo, have from 1860, to 1870, a year or two since, are less considerable, and prosperity than in the past. We have decided here that in most of the

[illegible]

There are several spas and two canals. A woolen hosiery factory at Cambridge; and catholic seminary at Maynouth St. above 300 students.

7809. KING'S COUNTY 457,000 acres, half of it bog, mountain, and waste, and the remainder arable meadow and pasture, of a medium quality (Census Agricultural Survey 1891. Sup. Enquiry Brit.

[illegible]

been erected by some of the proprietors, were for some time allowed to stand unoccupied.

The house was formerly the thirty-one years, or three lives but the more numerous period of late in twenty years. It was wholly destroyed by fire in 1870, and the land of it is now a public school. Some tenants hold for lives renewable for ever, paying a nominal sum equal to half a year's rent, or more, on the day of every five. Modern houses over compete prohibition against alienation. Nothing is so much complaint of among the country as the trade in, with the alienation of, the land. The country is now the hands of managers, no farmers, and no property vested.

7870. QUEEN'S COUNTY 364,000 acres, generally of a level surface, three fourths of which is of a productive soil cultivated, and the rest bog and waste. (Cook's *Agricultural Survey*, 1801. *Sup. Encyc. Brit.*)

[illegible]

best farming in Ireland, with much more attention to a systematic course of cropping, and to husbandry of the land in good heart. Oxen and horses are used for the purpose, the former being generally preferred to the latter. A good deal of manure is made from the straw of the corn, and the manure is used in the most judicious manner. The soil is not so rich as in some of the other counties, and is generally described.

The manufacturing age linen and coarse woollens, but to a great extent.

7971. CARLOW 280,000 acres, of undulating surface, with some hills and mountains the lowlands a fertile loam, and the uplands a light gravel one tenth in mountains and bogs (*Walsby's Statistical Account, & Young's Tour &c. Sup. Engrs. Brit*)

[illegible][illegible]

**7898. SLIGO.** 327,000 acres, a third part bog, mountains, and waters, and the remainder fit for tillage or grazing. (*Mr. Forster's Survey of Sligo, 1803. Wakefield. Sup. Enqy. Brit. Edin. Gen. 1837*)

The soil is generally of a light, sandy, gravelly loam, or sandy; in some parts the loam is rich and fertile, but the soil of a considerable part is gravelly, previously to the commencement of vegetation. Mountainous districts and hills; the wooded lands and moorland except Lough Gill, very fertile. On the hills and bog, considerable numbers of sheep; some sheep and cattle fed on the moorland. The number of sheep is about 200,000. A few are worth from 2000. to 3000. a year; but the greater proportion of the county is devoted to the raising of sheep. The number of cattle is about 100,000. There are few horses, and these are generally of the Irish breed, and are not much valued for riding or for the carriage. The number of horses is about 10,000. The number of pigs is about 10,000. The number of geese is about 10,000. The number of ducks is about 10,000. The number of turkeys is about 10,000. The number of geese is about 10,000. The number of ducks is about 10,000. The number of turkeys is about 10,000.

**7899. CAVAN.** 430,987 acres, almost entirely covered with hills; the surface, soil, and climate, being all black and unproductive. There are no fewer than 91 bogs, occupying 17,800 acres. (*Coote's Survey of Cavan, 1801. Wakefield. Sup. Enqy. Brit. Edin. Gen. 1837*)

Now Fermanagh, the appearance of the country is favorable; the hills are not so high, and the soil is not so black as in the other parts of the county. The number of sheep is about 200,000. The number of cattle is about 100,000. The number of horses is about 10,000. The number of pigs is about 10,000. The number of geese is about 10,000. The number of ducks is about 10,000. The number of turkeys is about 10,000.

**7900. FERMANAGH.** 450,000 acres, in great part covered by water and the rest of the rest of the surface rugged and mountainous but better wooded than other parts of Ireland. (*Wakefield. Sup. Enqy. Brit. Edin. Gen. 1837*)

The soil is of a light, sandy, gravelly loam, or sandy; in some parts the loam is rich and fertile, but the soil of a considerable part is gravelly, previously to the commencement of vegetation. Mountainous districts and hills; the wooded lands and moorland except Lough Gill, very fertile. On the hills and bog, considerable numbers of sheep; some sheep and cattle fed on the moorland. The number of sheep is about 200,000. The number of cattle is about 100,000. The number of horses is about 10,000. The number of pigs is about 10,000. The number of geese is about 10,000. The number of ducks is about 10,000. The number of turkeys is about 10,000.

**7901. MONAGHAN.** 298,500 acres of low grounds, with detached hills, and a considerable space occupied by bogs and small lakes. (*Coote's Survey of Monaghan, 1801. Wakefield. Sup. Enqy. Brit. Edin. Gen. 1837*)

There are a few bogs, but the greater part small ones, many of which are covered with a few trees, and are only fit for the raising of sheep. The number of sheep is about 200,000. The number of cattle is about 100,000. The number of horses is about 10,000. The number of pigs is about 10,000. The number of geese is about 10,000. The number of ducks is about 10,000. The number of turkeys is about 10,000.

**7902. TYRONE.** 515,440 acres in great part mountainous and containing, among other mountains, Ben Bulbin and Ben Bulbin. The territorial value of this island and northern district is much inferior to that of most districts. (*Mr. Forster's Survey of Tyrone, 1803. Sup. Enqy. Brit. Edin. Gen. 1837*)

Various valuable bogs, but the greater part small ones, many of which are covered with a few trees, and are only fit for the raising of sheep. The number of sheep is about 200,000. The number of cattle is about 100,000. The number of horses is about 10,000. The number of pigs is about 10,000. The number of geese is about 10,000. The number of ducks is about 10,000. The number of turkeys is about 10,000.

**7903. DONEGAL.** 1,200,000 acres of rugged, boggy and mountainous surface, with a cold, wet climate, and neither wholly nor partially fit for tillage or grazing. (*Mr. Forster's Survey of Donegal, 1803. Wakefield. Sup. Enqy. Brit. Edin. Gen. 1837*)

Stated by a man who walks backward before them. One, two, and perhaps are the principal crops. Of the two former a good proportion is consumed by Irish population, which, within these few years, has increased in almost every part of the county. It was to the value of their sheep that many of the small tenants looked in the season of selling their stock. In some parts, both cattle and sheep are kept in considerable numbers, and a great deal of butter is supplied from the farms of the county; but the land occupied in this way is not a small proportion to the whole; it is given over to the raising of sheep. The number of sheep is about 200,000. The number of cattle is about 100,000. The number of horses is about 10,000. The number of pigs is about 10,000. The number of geese is about 10,000. The number of ducks is about 10,000. The number of turkeys is about 10,000.

Through the very tops of the hills are filled, yet it does not appear that this country produces more grain than is necessary for its own consumption; nor has the honey on the inland portions of the county been increased by the raising of sheep. The number of sheep is about 200,000. The number of cattle is about 100,000. The number of horses is about 10,000. The number of pigs is about 10,000. The number of geese is about 10,000. The number of ducks is about 10,000. The number of turkeys is about 10,000.

more productive than in most other parts of Ulster. One, two, and perhaps are the principal crops. Of the two former a good proportion is consumed by Irish population, which, within these few years, has increased in almost every part of the county. It was to the value of their sheep that many of the small tenants looked in the season of selling their stock. In some parts, both cattle and sheep are kept in considerable numbers, and a great deal of butter is supplied from the farms of the county; but the land occupied in this way is not a small proportion to the whole; it is given over to the raising of sheep. The number of sheep is about 200,000. The number of cattle is about 100,000. The number of horses is about 10,000. The number of pigs is about 10,000. The number of geese is about 10,000. The number of ducks is about 10,000. The number of turkeys is about 10,000.

**Local property** is in few hands. The soil is a very heavy black slate in Duncannon. The use of the plough is confined to a small proportion of the cultivated land, and is generally done by the tenant. The soil is very poor in most places. It is only in the chief potato crop, and it is almost all used in distillation, that any crops are grown for exportation, and wheat is produced in the few fertile spots. There are not two farms in the county. The cultivation of the soil is in the hands of the tenant, and is confined to the potato, barley, oats, and other crops. The potato is the chief crop, and is raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation.

The crops are growing; and in many parts they are allowed to grow for several years in the same place. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation.

**7698 LONDONDERRY** 510,780 acres, generally mountainous, fertile and beautiful in the valleys, and containing every variety of soil. (*Sampson's Survey of Londonderry 1802. Wakefield. Sup. Enquiry. Brit. Edn. 1857*)

**Local property.** With the exception of lands belonging to the church, and the town of Londonderry, and certain portions reserved by the crown to be afterwards erected into franchises, the whole of Londonderry was granted, by James I. to the twelve companies or guilds of London. The estates are, therefore, held from these companies, either in perpetuity, or on condition of purchase. The principal proprietors or leaseholders are Lord's of Londonderry, Lord's of Londonderry, and the Lord's of Londonderry. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation.

The principal crops are potatoes, barley, oats, and flax. Wheat is not in general cultivated. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation.

**7699 ARMAGH** 203,871 acres of varied and rather interesting surface of mountain, plain, and bog; with rivers, streams and lakes, and a climate mild for the latitude. 594,000 acres are set aside fit for cultivation. The celebrated George Ennor is a native of this county, and resides on his own estate at Loughgal, near Armagh. (*Coote's Survey of Armagh, 1804. Wakefield. Sup. Enquiry. Brit. Edn. 1857*)

Marked by an uneven quality and of great beauty, is wrought in Armagh. The chief of the mountains called the Fews, which divide the county, is the highest, present many highly fertile and productive soils. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation.

One cow is considered as the average produce. The proportion of the milk cows to the size of the district is on an average under five acres, one cow on farms exceeding five, and under ten acres, perhaps one cow. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation.

**7694 DOWN** 538,595 acres, of which one eighth are mountainous and waste, the remainder hilly and productive, cultivated by small manufacturers, and neat white washed habitations. The climate is variable, but not subject to extremes. (*Dubouche's Survey of Down, 1802. Sup. Enquiry. Brit. Edn. 1857*)

**Local property.** There are some large estates, though in general it is much divided, and has all the different gradations from the most fertile to the most sterile. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation.

There are extensive pastures on the banks of the River and the Lagan. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation. The soil is very poor, and the crops are raised in great quantities for exportation.

**7695 ANTRIM** 692,020 acres on the east and north mountains, destitute of plantations, and abounding in bogs, the other parts more level and fruitful, and the climate drier than in some other counties. (*Newcomen's Statistical Survey. Wakefield. Dubouche's Survey of Antrim, 1815. Sup. Enquiry. Brit.*)

1778. Andrew, James LL.D. an eminent agricultural writer, was born at Hermiton a village near Edinburgh in 1730, on a farm which his parents had possessed for some generations, and which he was intended to inherit and to cultivate. He lost his parents at an early age but his education was not neglected he studied chemistry under Dr Cullen, and soon leaving his farm near Edinburgh took one in Aberdeenshire of 1500 acres, which, after improving and cultivating for twenty years, he let, and enjoyed an annuity from it during his life. He settled, after leaving Aberdeenshire, in the neighbourhood of Edinburgh where he published the Bee, in weekly sixpenny numbers, till it extended to 18 volumes. In 1797 he removed to Isleworth near London, where he published Recreations for the Agriculturist, in six volumes, and his Description of a Prussian Husband. Here he enjoyed his garden, and died of a decline in 1808, aged 69. Besides the works which bear his name he wrote the reviews of books on rural matters for the Monthly Review for many years.

The Present State of the Husbandry in Scotland. Edinburgh, 1778. 8vo.

1777. Black, James, of Morden, Surrey a surveyor in his day in great practice.

Observations on the F. of the Earth, and on the Theory of Instruments adapted to the use of the Land. London, 1777. 8vo.

1778. Marshall, William, Esq. a native of Yorkshire, brought up to trade, he was some years in the West Indies, as a planter, returned about 1775, and took a farm in Surrey, went down into Norfolk as agent to Sir Harbord Harbord's estate in 1780, he left this situation in 1786, and went and resided at Stafford, near the junction of the four counties of Leicestershire, Warwick, Stafford, and Derby where he remained till 1786, occupied in collecting materials for his *Economical Survey*, and in printing some of his works. From this time till about 1808, he resided chiefly in Clements's Inn, London in winter and visited different parts of the country during summer. He spent one summer in Berkshire, chiefly on the Earl of Breadalbane's estate at Teymouth and partly also on the Earl of Mansfield's at Soham. He proposed arrangements for the tenable land and also the park and woody scenery on various estates, and finally retired to a considerable property he purchased in his native country in the vale of Cleveland, in 1808, where he died at an advanced age in 1819. He was a man of little education, but of a strong and steady mind, and pursued in the most consistent manner, from the year 1780 to his death, the plan he originally laid down; that of collecting and condensing the agricultural practices of the different counties in England with a view to a general work on *Landed Property*, which he published another on *Agriculture* which he did not live to complete and a *Rural Institute*, in which he was supplanted by the Board of Agriculture.

1. Minutes of Agriculture made on Farm of 800 acres, of various soils near Orpington Surrey. London, 1778.

2. Experiments and Observations concerning Agriculture and the Weather. London, 1779. 4to.

Observations on the Disease which has lately been so destructive to sheep, called *Bane* or *Cott*; particularly the Causes, and in many, describing the Modes of effecting its Cure; and pointing out those Means which ought to be adopted to prevent its Recurrence. Bath pamph. 8vo.

## SECT. II. Bibliography of Agriculture in Foreign Countries.

7699. Numerous works on agriculture are published in the French and German languages, and a considerable number in the Italian; but a great proportion of these are translations from British authors. Very few agricultural books have been printed in the Dutch, Flemish, Danish, Swedish, Polish, Spanish, or Portuguese languages, and scarcely any in those of Russia or Hungary. We shall notice the principal French, German, and Italian works, exclusive of translations, and add a few American books.

### SUBJECT 1. Bibliography of French Agriculture.

7700. Of French books on agriculture we have given a selection only those who wish to see a complete list are referred to the *Bibliographie Agricole*, Paris, 8vo; in which are given the titles of upwards of 8000 works, including translations and books on gardening. A general idea of French culture in all its branches may be obtained from the *Nouveau Cours Complet d'Agriculture* of the French Institute each of whose names are given to the articles he contributed.

1793. *Ricome, Charles et J. Lichet*, physicians *Ricome, Le, Sieur* or *Sieur*, in the beginning of the sixteenth century published various small tracts on Gardening and other rural topics and in 1820 he collected them together and published them, under the title of *Practical Rusticism*, treating of gardens, trees, vines, herbs, manures, lakes, forests, orchards, &c. Having married his daughter to Lichet, they afterwards studied agriculture conjointly and published the *Manuel Rustique* the modern editions of which are still the most popular agricultural works in France.

1. *Practical Rusticism* in 4 vols. Paris, in 4to, 1870.

2. *Manuel Rustique*, or *Practical Rusticism*. De l'Art et de l'usage de l'agriculture rustique, ou de l'usage de l'agriculture rustique, ou de l'usage de l'agriculture rustique, &c. &c. Paris, in 4to, 1870.

1793. *Stephens, George* draught member of the *Keweenaw and Wernickishka Agricultural Societies in Sweden*.

The *Practical Carpenter* being an Account of the Utility, Formation, and Manner of Draining Meadows, with Particular Account of the System of Draining in Scotland. To which is added, a Practical Treatise on strengthening

1800. *Servet, Olivier de la* Lord of *Pradel* in *Langueadoc*. He was born in 1559, and died in 1619, at the age of 60 years. He was employed by Henry IV. to form a plantation of the white mulberry in the garden of the Tuilleries and he is generally considered as the father of the culture of that tree in France. He published a great many useful works the principal of which is his *Traité d'Agriculture* the first edition of which was published in 1660, and the 20th in 1875.

Le *Viticulteur d'Agropolis* et *Manuel des Champs*. Paris, small 8vo. An enlarged edition in 3 vols. 8vo. 1875. *Revue des Sciences*, and *Revue des Sciences*, in 1874.

1800. *Yvelier*.  
*Revue des Sciences* et *Manuel des Champs*. Paris, small 8vo. An enlarged edition in 3 vols. 8vo. 1875.

1804. *Lafayette, Benjamin de*, valet de chambre to Louis XIII.

Le *Viticulteur d'Agropolis* et *Manuel des Champs*. Paris, small 8vo. An enlarged edition in 3 vols. 8vo. 1875.

1807. *Picot, Elie* a learned professor of *Ban*. *Revue des Sciences*, and *Revue des Sciences*, in 1874.

1693. *Paris, Charles*, son of a physician of that nation.

1708. *Liger, Louis* born 1658, died in 1717. In the latter part of his life he seems to have been a bookseller, or an author by profession.

1. *Dictionnaire Général des Termes propres à l'Agriculture, avec leurs Définitions et Synonymes.* Paris, in 12mo.

2. *La Nouvelle Méthode pratique, ou Sommaire Général des Sciences de la Concomme.* Paris, 3 vols. in 4to. 1745.

3. *L'Économie Générale de la Campagne, ou Nouvelle Méthode rurale.* 1768.

4. *Notions générales d'Agriculture.* 3 vols. in 8vo. 1776.

1740. *Boucher d'Arg, Antoine Gaspard*, advocate and author of some works on jurisprudence.

1. *Code Rural, ou Maximes et Règlements concernant les Biens de la Campagne.* 3 vols.

1745. *Bacquerot René Antoine Forchault*, clerk of a learned naturalist, born at Rochelle in 1683, died in 1767.

1. *Art et Pratique de l'Art de faire des vases en terre, des Vases d'Économie de toutes Espèces.* Paris, Imprimerie Royale, 3 vols. in 12mo, avec fig.

1750. *Baronnet Du Motteux, Henry Louis* de, a famous French writer on Rural Economy and Vegetable Physiology was born at Paris, 1700 died there 1782.

1. *Traité de la Culture des Terres.* Par 6 vols. 12mo.

2. *Éléments d'Agriculture.* Par 1764. 3 vols. 12mo.

3. *Traité de la Conservation des Grains, et en particulier du Froment.* Par 1764. 12mo.

4. *Traité des Arbres et Arbustes, qui se cultivent en France, ou plus d'un.* Par 1756. 4 vols. 8vo.

5. *Traité complet des Bêtes et des Arbres.* Par 1766. 6 tomes.

6. *Des Bêtes et Plantations des Arbres et de leur Culture.* Par 1760. 4to.

7. *Méthode d'un lavage qui donne les Grains de l'Europe.* Par 1762. 12mo.

8. *De l'Économie des Bêtes ou Moyen de leur Fournir de l'Aliment.* Par 1764. 2 vols. 8vo.

9. *Méthode sur la Culture et la Culture, in 4to. 1763.*

10. *De l'Économie, de la Conservation, et de la Fourniture des Bêtes.* 1767. 4to.

1781. *Dezobry Pierre Alexandre Aubert de la Chesnaye* a laborious Dictionary maker was born at Ermené in the Maine, 1693; died 1764.

1. *Dictionnaire d'Agriculture.* 3 vols. 8vo.

1765. *Blancet Hilarion* de la Prince de Conti lived at Paris, in 12mo.

1765. *Tillet* de, de Bourdeaux, a zealous agriculturist, author of several works. He died in 1791.

## SUMMARY 2 *Bibliography of German Agriculture*

7501. The German *agricultural works* are as numerous as those of the French, but chiefly translations, and these, for the most part, from the English. We have given a very limited selection; the German language being less generally understood than either the French or Italian. In forest management (*Forstwissenschaft*) the German bibliography is very rich, and it is chiefly these books, and descriptions of local practices, which can be of any interest to the British cultivator. The older German works in rural affairs are enumerated in Haller's *Agriculture*, and the modern ones and new editions in Erpel's *Vorlesungen über Landwirthschaft*. *Lehrbücher*, and the *Landwirthschaftliche Encyclopädie* of Meissner are the highest in esteem as general works, while Scheller's *Deutsche Landwirthschaft*, a voluminous work will give a general idea of every part of German husbandry.

1578. *Hersbachius Conradus*, counsellor to the Duke of Cleve was born in 1508, died in 1578. He wrote various theological works, besides his *Bei Rusten* libri iv which was published in 1570, and his *Legum variorum et Operum per singulos Menses digesta*, in 1556. The former was translated by Barnaby Googe, of Lancashire, with the following title:—

Four Books of Husbandry, contain the whole Art and Trade of Husbandry, Garding, and Graffing, and Planting, with the Antiquities and Commendation thereof Newly Enlarged and improved by Horatio George, Acquire at London, 4to 1678. Lovers 134. teaches the Medication of the besting, and of Old English Rales in Venice for your children,ounds at the end

His authority as extended from the Bible to doctors of the church, through the Greek and Roman writers, Homer, Catu, &c. to the moderns as low as Barclay, Pachius, Matthiolus, Cardanus, and Tragus. He subjoins a list of his friends and others who assisted him. S. Nich. Malton, M. Cap. Eyngham, M. John Somer, M. Anna Yetstrout, M. Fyberghert, M. Wille Lambert, M. Jamer M. The Whetnall, M. R. Deering, M. Hen. Brooklin, M. Franklin, H. King, Richard Andrews, Henry Deery, William Pratte, John Hatches, Philip Farbridge, Kenneth Dextrah.

The work is in dialogue. The persons are Cono, a gentleman retired into the country, Rego, a courtier Metella, wife of Cono and Herman, a servant.

1908. A number of Italian agricultural works have been published; such as they are, perhaps none of them are original than of the books on the French or German lands. The statistics of other parts of Europe is hardly adapted for Italy. The vine, olive, mulberry, orange, and the irrigation of lands have a good deal occupied the Italian writers. But may be reckoned their general and popular author and has *Numeri Elementari*, 6 vols. 8vo, 1815, and *Annali del Agricoltore*, etc. 2 vols. 8vo to 1816, will give a good idea of Italian husbandry and gardening, the two arts in that country being for the most part combined.

#### Summary 4. Bibliography of the Agriculture of the other Countries of Europe.

7000. *Germany and Britain* are the only countries in Europe in which it answers to print agricultural books for the sake of the malignancy of the sun. In Britain, education is so general among the middling and lower orders, that reading among them is a necessary convenience of life, in Germany education and reading are equally general and essential and consequently in neither of these two countries a book will pay by its sale within the country. But this is not the case in any other European country. In France the mass of the people do not read, but books printed there pay, because they are in a language more universal than any other and perfectly understood by all men of education in Europe. Italian books pay, because they are required for by the agriculturists of the south of France, all Spain, and in part of Spanish America.

7004. *Spanish and Portuguese books on agriculture* are in much too limited a demand for production. The earliest Spanish author is Herrera, in 1596, and there are scarcely half a dozen since. After the most particular researches of a book agent at Madrid, he was only able to send a list of translations, and the translations of the *Economical Society of Madrid* who have also published Herrera's work with notes within the present century. In 1816, a professor at Madrid published *Lecciones de Agricultura* conchas en el Jardín Botánico 2 tomos 4to. An anonymous author *Desarrollando sobre varios Plantes Agrícolas*, 1 tom. 4to. Of Portuguese books we could hear of none.

7005. *Of Flemish and Dutch books on agriculture* there are scarcely any. These languages are very limited, and every reader in Holland or Flanders understands French or German. Many works have been published in the Low Countries in Latin and French, but these cannot be considered indigenous. The few Dutch works on culture belong almost all to gardening (*Boepje of Goe 1763*). The result of our correspondence with Amsterdam is a *Nieuwe Maatschappij van Wetenschappen*, 2 toms. 4to., from which we can little worth taking. There are several translations from British works on culture and French veterinary books, and the following seem the latest on husbandry.

*Magazine van Vaderlandschen Landbouw* door J. Kops, Commisaris tot den Landbouw (Gedeen compleet met register).

*Aanwijzing ter verbetering van de Akkerbouw en Landhuisboekkunde, in de Nederlanden*, door Professor A. Bruchmann 3 Gd.

De *Rekenen Geschiedenis*, of kunst, om van verschillende soorten van Landbouw, het meeste nut te trekken, naar Vor te kunnen bepalen, en andere Wetenschappelijke tot den Landbouw door J. F. S. reuter en J. Kops, met platen.

*Lichtende, of P. de, Rekenen of the Royal Society of Agriculture and Botany of the city of Ghent: Le Mérite, en la Mérite de la Flandre Occidentale*. Brussels, 1800.

*Collo, M. P. M. D. et Liège* Instructions sur la Fécule des Marais, ou, Moyen d'augmenter les Cultures en faisant couler les Marais dans les Champs. Liège, Fanchin 8vo.

7006. *Of Swedish and Danish books on agriculture*, there are necessarily very few. These languages being of very limited use, and the mass of the people too poor to be able to afford to read about ordinary matters, or what they consider as already well known to them. The few such a people give to authors will be devoted to religious subjects, legends and romantic poetry or history. The universities of Stockholm and Uppsala, every one knows, have produced some useful naturalists. Some of these have

written treatise on agricultural improvements, especially on planting fruit-trees (*Recht-Frucht*) and cultivating military vegetables (*Kriegs-od. Kriegsg.*). A few of such works we have enumerated in our *Index*, *Index* of Gardening (1788), but we can scarcely find any fit to be inserted here as agricultural. The *Natural and Chemical Elements of Agriculture*, by Count Gustave Adolphe Sjöström, a learned Swedish statesman, were translated by John Mills in 1770, and may be considered as the prototype of Davy's *Agricultural Chemistry*. There are several treatises on the culture of the potato in the *Swedish Transactions*; also on tobacco, on the management of sandy soils, on the cultivation of the Carrot; and on the hop and plants for fodder.

1825. *Ann.* : Kongl. Svenska Lärarhögskolans Akademiska Årsbok. Year 5. Part I. 8vo.  
1828. *Strömberg, M.*, machinist to the king at Fredericksborg, near Copenhagen. Affidavit of the books of nyeste Agerdyktningsskribat, &c. Copenhagen. 4to.

1787. *Of Polish and Russian books on agriculture*, it may be justly concluded, there are very few. Some translations from French works were made into the Polish language under Fried. Augustus II.; but few or none since that time, the German or French being universally understood by the reading class. Books of agriculture in the Russian language could be of little use. The only things printed in that way there are in the transactions of the Economical Society of St. Petersburg, by foreigners resident there, and in Latin or German. The best informed Russian angles read French or German like the Poles. There is an agricultural society at Warsaw, which occasionally prints its transactions; and another has lately been established at Moscow, which publishes an agricultural newspaper. (*See Germ. Mag.* vol. I. and II.)

1825. *Farley, M.*, Zemledelitschenskaia Chinita, Moscow 8vo.  
1825. *Arnski, M.*, a nobleman possessing one of the largest houses in Moscow; Zemledelitschensky Journal, &c. Moscow 8vo.

1825. *Ann.* : Avantages résultant de l'introduction de la Culture variée des Turres. Warsaw 8vo.

### SUBJECT 5. Agricultural Bibliography of North America.

1708. *There are a few American books of agriculture*, and republishations there of most of our best works on the subject. *Dean's New England Farmer's Dictionary* may be considered as giving an idea of the husbandry of that part of the country and *Baughley's Journal* a picture of the agriculture of the West India Islands. A number of interesting papers on the subject will be found in the transactions of the American, New York, Philadelphia, and other societies.

1744. *Burrows, John, M.D.* Philadelphia.  
On the Salt Marsh Mould. On Oyster Banks and the Fresh Water Mould of Pennsylvania. (*Phil. Trans.* &c. &c. p. 70.)  
1764. *Planning or Planning Malcolm, M.D., of Bragg.*

A Proposal in order to demonstrate the Progress of the Plantations among the Colonies. supported by Phil. Trans. &c. &c. p. 70.

1755. *Baughley, William.*  
A Treatise upon Husbandry and Planting. Boston, New England. 4to.

1764. *Edmond.*  
Hints upon the Husbandry in New England. Lond. 4to.

1779. *Carver, Jonathan, Esq.* born in America in 1738, died at London, 1780, in great poverty.

A Treatise on the Culture of the Tobacco Plant, with the manner in which it is usually cured, adapted to Northern Climates, and designed for the Use of Luncheoners of Great Britain, with two Plates of the Plant and its Flowers. Lond. 8vo.

1780-1808. *Ann.*  
Minutes of the Philadelphia Society for promoting Agriculture; containing Communications on various Subjects in the husbandry and Rural Affairs. Philadelphia. 8vo.

1780. *Aspell, Hon. Edward, Esq.* of New Jersey.  
An Essay on the cultivation of the Vine, and the making and preserving of Wine, mixed to the different Climates of North America. (*Amer. Trans.* I. 181.)

5. The Method of sowing Potatoes and Observations on the raising and dressing of Hemp. (*Id.* I. 185.)

1789. *Burrows, M.D.*  
Observations on the Native Oak Worms of North America. (*Amer. Trans.* I. 184.)

1789. *Carver, Jonathan, Esq.* of Sabine Hall, Virginia.  
Observations concerning the Fly-wool that destroys the Wheat; with successful Remedies and Conclusions. (*Trans. Amer. Soc.* I. 174.)

1790. *Down, Dr.*  
New England Farmer's Dictionary.

1795. *Higgins, Jesse, of Delaware.*  
A Method of draining Fields in Low Grounds. (*Trans. Amer. Soc.* vol. II. p. 280.)

179. *Greenway, Dr. James, of Dinwiddie county in Virginia.*

Of the Beneficial Effects of the Chain Churners in various cases of Lungs, and creating such as are necessary. (*Trans. Amer. Soc.* II. p. 234.)

1800. *Dezobry.*  
Le Science du Cultivateur Américain. Ouvrage destiné aux Colonies et au Commerce. 8vo.

1801. *Baughley, J. B.*  
Hints and Notes on Husbandry and Rural Affairs. Philadelphia. 8vo.

1812. *Barton, Benjamin Smith, M.D.* professor of natural history and botany in the university of Philadelphia.

On the Native Country of the Tobacco tobacco, or Potato. (*Id.* Jan. 1812.)

1811-1816. *Ann.*  
Minutes of the Board of Agriculture of the State of New York. Albany 8vo. 4 vols. to 1816.

1822. *Fredericks, Thomas G.*  
The New England Farmer; containing Hints, original and selected, relative to Agriculture and Domesticity, with Engravings and the Prices of Country Products. Massachusetts. 4to. 4to. 1822.

1825. *Baughley, Thomas*, nearly twenty years a sugar planter in Jamaica.

The Jamaica Farmer's Guide; or, System for planting and managing a Sugar Estate or other Plantations in that Island, and throughout the British West Indies in general. Illustrated with interesting Anecdotes. 8vo.

1825. *Ann.*  
The Ploughing Vol. II. 4to.

1825. *Ann.*  
Massachusetts Agricultural Repository and Journal. 7 vols. 4to.

1828. *Ann.*  
New York Farmer and Horticultural Repository. New York 4to.

1828. *Lathrop, E. L., Esq.*  
The Farmer's Library; a Series of Essays and Papers for the Promotion of the Study of Agriculture. (Windsor, U. S. 1828.)

## CHAP V

### Professional Police and Public Laws relative to Agriculturists and Agriculture.

7909. *By professional police* we mean those associations which agriculturists have formed at different times and in different manners, for mutual benefit or instruction; and also those institutions for the same purpose established by the legislature, or of such a nature as to be considered public or national. By laws we allude to those special legislative enactments which affect more particularly agriculture. These are so numerous that we must refer the reader to his lawyer or law dictionary.

7910. *There are few or no agricultural bodies of the nature of those of necessity for gardening.* In Scotland it would appear something of this kind had existed among ploughmen at one time, as the parchment and military coronations are talked of in some of the counties by old men. In Fife, *Edinburgh, Sheriff,*

As it is less common for sheepmen, as well as various descriptions of operatives, to belong to gentlemanly orders. In the southern districts where sheep farming is followed there are some sheepmen's societies for mutual interchange of experience, and still in some of such sheep as are the sheepmen's property. There are some sheepmen's clubs in different places, and various associations among them of the nature of sportsmen's clubs; but these do not come under the description of professional.

7011. Agricultural societies for interchange of knowledge are of modern date, but they have increased rapidly since 1784. The number at present or lately existing in the British Isles is at least equal to the number of the counties. Societies of this description are either general, as the Board of Agriculture and Society of Arts; national, as the Highland Society and Dublin Institution, particularly, as the Bath and West of England Society provincial, as county societies or parochial, as being limited to a few individuals within one parish. Of this kind are farmers' clubs, ploughing societies, &c. In regard to the end in view, these societies either embrace the arts in general, the rural arts in general some branch of the rural art, as agriculture; or some department in that branch, as live stock, sheep, wool, &c.

7012. All these societies hold meetings at stated periods. Most of them offer premiums for particular objects,—specimens of vegetables or animal culture or products, agricultural operations, manual and professional marks, as carvings, &c., some of them form a library and museum of models or full-sized implements, a few publish transactions, and one or two, as the Dublin Society send itinerant ploughmen and agricultural mechanics to instruct practical farmers. These societies are almost wholly supported, and the funds for premiums raised by the subscriptions of members, and by voluntary donations, legacies, &c. but some, as the Board of Agriculture and the Dublin Society have received assistance from government.

7013. Of English agricultural societies the oldest is the Society of Arts, founded in 1754 by Lord Folkestone, Lord Romney, Dr Hales, and Shepley. They have published many volumes of transactions, awarded immense sums in premiums, and on the whole done much good. (See *Notes & Opns.* art. Society.)

7014. The Bath and West of England Society was founded in 1777 for purposes similar to those of the London Society of Arts. They have published some valuable volumes of transactions, and distributed various rewards, but (*Notes & Opns.* art. Soc.)

7015. The Board of Agriculture was founded, under the authority of government, in 1785. Much was expected from this board, but except the publication of the county reports, and the general attention which it called to agriculture, it may well be asked what advantages arose from it. Their Commission, in several parts, contains some very valuable papers, in particular in their total number, than the publications of either the London Society of Arts or the Bath Society, and it has been, *chit down*, in *The Farmer's Magazine* and

the article *Agriculture* in the supplement to the *Encyc. Brit.* that the Board never directed its efforts to a measure suitable to its power and consequences, and that, instead of stimulating modes of culture, its attention ought to have been directed to the removal of the political obstacles to agriculture, and to the stimulating of agricultural talent by literary rewards, &c. 'N' does it more erroneous than that of such a board, or any other, doing much good by a national experimental farm? The government withdrew its support from the Board about 1816 and there being no longer funds for handsome salary for a secretary it paid after 1816 to private, and is now only named, at least by us, for its lofty pretensions and its worse than inability.

7016. Of Welsh societies there are only two or three, of inferior note, which have been already noticed in the topography of the country.

7017. Of Scotch societies the principal now existing are the Highland Society and the Dalkeith Farming Society.

7018. The Highland Society of Scotland was established in 1716, to consider the state of the highlands, to consider the means of their improvement and the preservation of their law usage. It is chiefly supported by the subscriptions of its members.

here, at a price such a year, and soon after its establishment it had a grant of £2000 from government. It has published 7 vols. of price essays and papers, and now extends its price to all the law counties of Scotland. (*Notes & Opns.* art. Soc.)

7019. Of Irish societies the principal are the Dublin Society and the Cork Institution.

7020. The Dublin Society was established in 1781 and more recently in 1784. Arthur Young observes, that it was the parent of all the similar societies now existing in Europe. But from Birmingham, he supposed it to have been sent (1775 and 1781), was established nearly ten years before. The Dublin Society, in its present improved state, is one of the most complete establishments of the kind. (*Notes & Opns.* art. Dublin.)

7021. The Farming Society of Ireland was established under the patronage of the Dublin Society, in 1800. The object is to improve the agriculture and live stock of the kingdom. (*Notes & Opns.* art. Dublin, 1801.)

7022. The Cork Institution, for applying science to the com-

mon purposes of life, originated in private subscriptions, about the beginning of the present century. It has since been incorporated, and has received the assistance of government. It possesses a house and large herbaria gardens, and under its auspices are delivered lectures on chemistry, botany, agriculture, &c. It is not, however, in a flourishing state, and has never been of much use.

7023. The principal county societies in the three kingdoms have been noticed in the topography of agriculture. Many of them were established several years before the Board of Agriculture.

7024. The only other institutions for the improvement of agriculturists and agriculturists are public professorships. Of these there is one in the university of Edinburgh, established in 1786 one in Dublin, supported by the Dublin Society one in Cork and one is destined to be established at some future period in Oxford, agreeably to the will and donation of Dr Stethorpe (1804 and 1786.) professor of botany there.

## BOOK II.

### THE FUTURE PROGRESS OF AGRICULTURE IN BRITAIN.

7025. The improvement of agriculture, like that of every art, manufacture, or commodity, necessarily depends on demand and production. A powerful or effectual demand will ensure produce, and excellent produce will, to a certain extent, create demand. A general taste of taste in coach or saddle horses will call forth a superior description of these animals, and superior animals will tempt purchasers, if the inhabitants of any district who live chiefly on barley or oats indicate a preference for wheat, and a willingness to pay for that grain, wheat will be produced, and so on. Again, as the object of every individual who engages in art or trade is to acquire gain, the advancement of an art will depend mainly on the profits it affords; an art or occupation which affords less than the average profits on capital will only be followed by such as, from habit or other reasons, cannot apply themselves to any thing better, but extra-profit

will commend both capital and skill. From these considerations it is obvious, that the improvement of agriculture depends on the profits on capital employed in it, on the taste of those who purchase its products, and on the knowledge of those who are engaged in agriculture as a profession. The first subject would lead us further into political economy than would be of much use in a work of this kind, and therefore we shall limit ourselves to a few remarks on the other topics.

### CHAP. I.

#### *Improvement of Agriculture, by refining the Taste of the Purchasers of its Products, and increasing the Knowledge of Agricultural Patrons.*

7926. *The desire of being comfortable is the first step towards improvement* but before any thing can be desired, we must know what it is. Man, when they know of nothing better, rest satisfied with what they have, and therefore one of the main sources of improving the taste both of those who purchase agricultural produce from necessity and of those patrons of agriculture who purchase from the conjoined impulses of necessity and choice, is the increase of knowledge. However paradoxical it may seem, discontent is the parent of all improvement, as certainly as the acorn is the germ of the future oak, or the time present that of all future times. The grand achievement of the present age, an eminent writer observes (Ezra's, Jan. 9. 1831) "is the diffusion of superficial knowledge" and on this diffusion, superficial though it may be, the progress of agriculture and of every other art depends far more than on any thing else.

7927. *In Scotland and Ireland could a taste for wheaten bread and butcher's meat be introduced generally among the operative classes, the advantages to agriculture would be immense.* Could the same persons be taught to desire a greater degree of cleanliness, light, and warmth in their cottages; a greater variety of potherbs, salads, fruits, and flowers in their gardens; and handsome dresses for their wives and daughters, how great the general benefit! Much may be done to bring about this change, by the example who are willing to reside on their estates and to take a little trouble. Building good and comfortable cottages, attaching proper gardens stocked with trees and plants from the domestic garden, and offering little premiums, or marks of distinction for keeping them in the neatest order, and for cleanly clothed well-bred children, would soon have a sensible effect. Attending to this kind of education which consists in teaching infants civility and politeness, with mutual respect and restraint as occasion requires and instructing grown children how to work at almost every thing likely to come in their way as done in the improved German and Swiss schools, would, independently of reading and writing, do a great deal to soften and humanise the peasant mind. Encouragement should be given to save money for unnecessary wants, or against old age and the certain effects pointed out of early marriages, followed by a numerous offspring. These and a variety of similar means would be productive of some change of taste in the operative part of rural society.

7928. *The introduction of manufacturing establishments, wherever it could be properly done, would contribute to the same effect.* Those who work at manufactures, and even common mechanics, generally live better and are better clothed and lodged, than the common country labourers. Therefore their example would be of use in introducing a salutary degree of luxury. "The endeavouring to impress on the minds of the lower classes the propriety of being contented with the simplest and cheapest fare, is extremely pernicious to the best interests of mankind. Economists ought not to be bestowed on those who are contented with mere necessaries on the contrary such indifference ought to be held disgraceful. A taste for the comforts, the enjoyments, and even the luxuries of life, should be as widely diffused as possible, and, if practicable, interwoven with the national character and prejudices. Time, as it appears to us, is the best mode of attempting the amelioration of the condition of the lower classes. Luxury, and if you will have it so, even wasteful habits, are incomparably better than that cold, sluggish apathy which would content itself with what can barely continue mere animal existence." Mr. Peel observed in the House of Commons that "he thought it one of the first duties of the legislature, to do all in its power to excite a taste in the humbler classes of society for those comforts and those enjoyments—these luxuries, he might add—of civilized society the desire for which, and the habitual possession of which, would form the best guarantee for their good conduct, and the best guarantee that the higher classes could have for the possession of their property and their power as at present enjoyed." (*Memoirs of Cottage Gardening, Hedges, and Architecture, &c.*) "In those countries," Ricardo judiciously observes, "where the laboring classes have the fewest wants, and are contented with the cheapest food, the people are exposed to the greatest violence and abuses: they have no place of refuge from calamity: they cannot seek safety in a lower station, they are already so low that they can fall no lower. On any deficiency of the chief article of their subsistence, there are few substitutes of which they can avail themselves, and death to them is attended with almost all the evils of famine" (*Supp. Supp. 3rd. art. Corn Laws*). Such is the case in Ireland, where, amidst the perils of the greatest riches and luxury the laborers are condemned to live on less than any other people in the world.

7929. *The taste of the superior patrons of agriculture is to be improved by visiting the best cultivated districts, reading agricultural works, attending agricultural societies, and, above all, by cultivating a farm, and establishing on it a systematic order and regularity in every detail.* Let ush observe the hedges, gates, verges of fields, and the beautiful rows of turnips of Berwickshire or Northumberland. Let us rectly visited farms of East Lothian, and the live stock of Leicestershire. But few are the proprietors of those who either employ a regular bailiff or domestic steward, and of those who do, how few who do not consult and foster them in their operations, or else neglect them and leave them to sink into that supreme state in which the uppermost wish is to enjoy the comforts of the situation with the least possible degree of exertion! Some proprietors desire to have their home farms managed with a view to profit, as the cheapest way of getting by slow motion, &c. These are useful patrons. A home farm ought to combine an elegant country style of management, buty horses, harness, implements, &c. well bred servants, and every thing in a superior style to what is seen on common farms. Particular attention ought to be paid to the buildings, which should combine architectural design, fitness, strength, and elegance: the roads ought to be like approaches to a mansion: the hedges like those of gardens: the green verges round the fields kept mown like lawns or grass walks, and the ditches, bridges, and gates as corresponding contrast. The same trees ought to be encouraged in proper situations, and correctly pruned; substantial, weathering fences should and be supplied: every operation on plants, or the ground, performed in a garden-like manner; and no individual of any species of stock kept, of which a drawing might not be taken and preserved as a beauty. Even the dress and deportment of the servants on such a farm ought to harmonize with the high culture, orderly display, and high keeping of the whole.

## CHAP. II.

*Improvement of Agriculture, by the better Education of those who are engaged in it as a Profession.*

7930. By education is generally understood that portion of knowledge which is obtained at schools; but in a more extended sense (as Mills observes), it may be defined the means which are employed to render men competent for pursuing the part which he undertakes to perform in life, with increased satisfaction to himself and others. Education may thus be considered as extending to every thing which operates on the body or mind, from the earliest periods of our existence to the final extinction of life. It is unnecessary here to embrace the subject in its full extent, but we shall offer some remarks on the education of practical men in general, on the professional education of an agriculturist, and on the general conduct and economy of his life.

*SECT. I. Degree of Knowledge which may be attained by Practical Men, and general Powers of the human Mind as to Attainments.*

7931. The limit and degree of education that we think ought to be given to every human being in this and in every country, and in every state of civilisation, may be thus defined. All the knowledge and accomplishments that a child's body or mind can use the whole of his knowledge and the art of teaching at the time, will admit, previously to the age of puberty; giving preference to those branches of knowledge considered the most useful, and those accomplishments and manners considered the most humanizing, by the wise and good of the age. It seems unreasonable to employ any child in aiming to procure the means of his subsistence, or that of his parents, before the age of puberty. Previously to that age, by means of infant schools, and of the adoption of the various improvements that have been recently made in modes of teaching, all that is worth knowing may be taught more effectually than common reading, writing, and arithmetic are, during the same time, by the common method. Man, so trained and instructed, and living under an enlightened government, will become as different an animal from what he is at present, even in Britain, as the most enlightened modern moralist and philosopher of Europe is from an African savage. "It is not necessary," says Lequien, writing in 1764, "to render an agricultural labourer a learned man;" but I am well assured, from my own experience, that the knowledge of every thing useful, and of much that is agreeable, both in knowledge and manners, is perfectly consistent with a life of labour in the fields. But hitherto the education of the labouring classes in the country has proved rather an obstacle to the development of reason than otherwise. Eight or ten years are employed in filling the head of a child with chimeras and prejudices, which twenty years of study will scarcely succeed in entirely rooting out. It remains for national philosophical institutions to destroy this national evil, and we shall one day have under the thatched cottages of the country humbly thinking men endow of solid reason, and capable at once of taking a part in the political and moral affairs of their country, and holding the plough or guiding the cart on their own farm. "Il faut," says this admirable writer, "que les premières leçons soient l'apprentissage des droits de l'homme, et qu'ils soient enseignés avec aucun mélange des principes du fatalisme et des fruits barbares des gothiques préjugés, de quelques espèces que ce puisse être. Les enfants de la maison et du boc sont tombés sous tous les intellects. Les droits de l'homme instruisent tous les individus, et l'après de le leur servir bientôt d'écueil pour en faire de sagesse imparfaite; grâces une fois, je le répète, ils ne s'émousseront jamais. Ils se concilient avec abaissement, et ils se fixent bien plus solidement que ces antiques assertions données sur le fol d'instinct, et transmises à travers les ténèbres des siècles les plus obscurs assertions ridicules, et qui pour la plupart, et avantagèrement comparés à toutes ces fautes de raisonnement et folles dont le néant alors déteint pour tous, et par conséquent se sont encore plus avantagèrement mis en parallèle avec ces maximes absurdes que l'homme ne pouvait admettre qu'en rejetant l'évidence, et en se dépouillant totalement de son intelligence et de sa raison. C'est par ce simple enseignement que s'éleva tout d'un coup dans nos campagnes une espèce raisonnable et libre. Sortis, par cette création morale, du chaos ténébreux, et de l'existence éternelle où, depuis le commencement des siècles, elle croupissait sous le joug de tous les impôts humains qui se précipitaient de la domine: nous la verrons une race nouvelle, intelligente et hardie, laisser un aspect incommensurable entre elle et les générations qui l'ont précédée." (*Les Principes de l'éducation*, par J. M. Lequien, Paris, 1782. *Practical Institutions; or an Outline of a Plan for a National Educational Establishment*, &c., and *Des Établissements pour l'Éducation Publique en Suisse dans le Wurtemberg*, et dans le Pays de Bade.)

7932. A high and equal degree of education has some powerful advocates in North America, and, it is thought by many, will, at no distant period, be adopted in several of the states. The *New York Daily Sentinel* and the *Working Man's Advocate* are two of several newspapers which support what are called "working men's measures." Among these the first and most important is a "republican education, free for all, equal for all, and at the expense of all; conducted under the guardianship of the state, at the expense of the state; embracing every branch of useful instruction, moral, intellectual, and operative, and extending to the entire protection, maintenance, and guidance of children and youth, male and female, without distinction of class, cast, or party, or reference to any of the arbitrary distinctions of the existing state of society." (*See Essay on Public Education*, New York, 1825; *Compt's Lectures on Political Economy*, as quoted in the *Speculator*, Dec. 4, 1820; and *Gov. Mag.* vol. vi.)

7933. The high and equal degree of education we consider to be as much the birthright of a child in a community where there is a high degree of civilisation, as food and clothes are its birthright in the rudest state of society; because, without it, a man or woman is cast into society without a fair chance of being able to govern those various and various end of happiness which belong to human nature under the given degree of civilisation; in short, without a fair chance of making the most of life. To introduce an ignorant youth into a highly civilised country under the supposition that he could obtain the requisite degree of prosperity and happiness, would be more absurd than to turn an educated child into a country of savages. This is one view of the subject, and it is a view on which all who can afford the expense act with respect to their own children. If we regard the subject in the light of humanity and the sympathy of one part of society with another, this principle will equally dictate the duty of bestowing, at the expense of the state, that good on others which we feel to be a good in ourselves, and which we are convinced would add to the general happiness. Viewed as a matter of public policy, and considering that the great object of every government ought to be, with reference to its subjects, their happiness and prosperity; and, with reference to other governments, its own stability; reason dictates the use of the most improved means for giving them each and that it would be prudent, no less than just, in government to be vigilant, so that every individual subject should have the degree of education above defined. Let, then,

therefore, exist in society who have not their minds sustained by the care and culture of school teachers, as their bodies are by the nourishment and clothing of their parents. The vulgar and ignorant owe this to the poor as a part of human nature; the benevolent, as sympathizing with the children they suffer; the enlightened, in order to raise them to their rank in the scale of creation; the rich, to give them a greater chance of possessing property in order that they may respect the property of others; the prudent, that they also may become prudent; and government, that they may not be made the tools of faction, foreign or domestic. (*Favoured Institutions, &c.*)

786. Knowledge gives power; and if one part of society has the degree of education desired, and the other has it not, it is evident that there can be very little sympathy between them. The existence of age shows the continual tendency of the powerful in wealth or in skill to oppress the weak; and the continual tendency of the weak to react by personal force, by cunning, or by numbers, on the strong. Materials so discordant can never form the basis of a sound, healthy and permanent state of society; the pure and ignorant becoming, under such circumstances, little better than slaves to the rich and enlightened. To guard them from their enemies and often finding them to be such, must and will rebel; and the result is, sooner or later a subversion of society. It would evidently contribute to the stability and harmony of society to moderate this action and re-action, by a more equal distribution of power; and, as knowledge gives power the most obvious and efficient way of attaining this end proposed is, by diffusing such a high and equal degree of school education as we have defined. It must be evident, we think, that the state of society which this degree of education will confer or bear production, will include in it every amelioration and happiness of which human nature, under any given circumstances, is susceptible. (*Ibid.*)

787. The knowledge of languages, history, geography, arts, sciences and literature which an agriculturalist, whether a ploughman, shepherd, bailiff, steward, or rent-paying farmer daily occupied with his profession, may acquire by his own exertions, provided he begins at the earliest moment, say at fifteen years of age, and continues to employ his leisure hours in reading till he is twenty or twenty-five, is by no means inconsiderable; not that he can or need become learned; but, if desirous, he may become generally intelligent, render himself fit, as far as conversation is concerned, for good society; prove instructive and entertaining to others by his conversation, and provide a reserve fund of enjoyment, by laying up a store of ideas for reflection in misfortune, disease, or old age.

788. The extent of leisure given to that part of mankind who are doomed to a life of mechanical labour or rather who suffer themselves to be doomed to it, has been questioned. It is said to render them dissatisfied with their condition to produce various other evils, and at all events in no way to add to their happiness or the good of society. To a man whose business in life is the mere mechanical performance of operations which any other animal might perform if furnished with hands, education is doubtless less necessary than to a man whose business is to direct the operations of others; but it does not follow, that though less necessary, it may not be highly useful. If for example it renders him dissatisfied with his condition, it will, at the same time, be more likely than any thing else to lead him to some proper mode of improving it or if almost unimprovable, education certainly will be more likely than a state of ignorance to teach patience and submission, by enabling him to reflect on the folly of grieving at what is inevitable, and the consequences of committing what is unwise or criminal to relieve himself. "The few Irish. Men who are sufficiently dissatisfied with their condition; those who know how to alleviate it by emigration, go to Britain or America; those who know nothing, stay at home commit acts of violence, and are hanged."

789. To decide as to the utility of knowledge to the operative parts of society would perhaps require a previous discussion of the question, "What constitutes happiness?" The general answer is, the exercise of all our faculties of body and mind; every one who has lived thirty or forty years in the world, knows that there is no such thing as absolute happiness. The French de Laage, a man of great natural gifts, with every advantage of person, birth, and wealth and in favour at all the courts of Europe; fond alike of war, literature, gallantry and agriculture, and who lived to be upwards of 80 years of age, has left on record that he was only perfectly happy two or three times in his life, and only for a few minutes each time. Forsyth (*Principles of Moral Science* vol. I. chap. 1.) says perfect happiness is a thing not to be thought of, and that all that man and woman can in order to make the most of their existence, is to occupy themselves and make progress in whatever they engage in progress in enjoyment, or approximation to happiness, is therefore the object to have in view.

790. The utility of knowledge to every human being is consequently, in our opinion, unquestionable, on the mere principle of adding to enjoyment; nor do we believe that there is more danger from excess of knowledge in any particular class of society high or low than there is from excess in their eating or drinking. A number of men possessed of property or power by inheritance, favour, or chance, who are very conscious that they never could have acquired those advantages by the common competition of talent and industry and who are in fact wrapt up in selfishness, are naturally jealous of the progress of knowledge; their secret maxim is to keep down the lower orders, and to impress on their minds only the duties of loyalty, religion, and, as Vancouver adds, hard work. This monopoly of power and knowledge, however cannot be maintained for ever, and in every country it is found rapidly yielding to the general progress of society. It is only those who have to dread this progress that fear the diffusion of education and liberal principles.

791. Education in all countries in as far as it has been carried, has had the effect of rendering the poor content. Compare the poor of Sweden and Germany with those of England. The uneducated are prone to consider wealth and happiness as synonymous, a delusion which knowledge quickly dispels, philosophy teaches its fallacy and history exemplifies it. For our own part, we can see nothing in education but increased security to the rich and increased happiness to the poor. One of the great evils which at present afflict society in this country is over-production; not only of manufactured goods, but also of human beings. We are apt to believe that even this calamity might be remedied, if every labourer in the country considered a high and equal degree of education as a necessary of life, and no more to be dispensed with in a child than food or clothing; as in that case he would not think of marrying till he could bestow this degree of education on his children. If any labourer asked otherwise, he would bring himself into disrepute among his own class; he would suffer a loss of reputation for good sense and good taste; and his wife and himself would no longer be able to associate with their neighbours, either from the extraordinary exertions which they must make, in order to educate their children up to the general level, or in consequence of not being able to do so, and having it done for them by the parish as paupers. The result of the reflection and sagacity of the children when they arrived at maturity and found that they were indebted to the parish more than to their parents for their education, and that they had, in fact, to pay the parish for this education themselves, would also act as a powerful inducement to parental conduct. Besides, when parents themselves have once enjoyed the degree of education defined, they will consider it cruel and unjust not to bestow the same degree of education on their children. This is, in fact, the feeling of all educated parents; and one great object that we have in view is to communicate the same feeling to the very lowest tier of society. We are justified in concluding that universal education would do so, by what actually takes place at present among the educated classes. (*Favoured Institutions, &c.*)

792. The *fruits* of knowledge and ignorance are entirely relative: the knowledge of a modern chemist's porter would have subjected him to be hanged and burned in the days of the first popes; and any labourer's labours at the present day who reads the London newspapers, has more correct notions of the principles of politics and science than any teacher of the village in Russia and Asia. It is in order to be able to use the knowledge which may be obtained by those who are destined even to the most arduous and constant labour: the intelligence of the miners in Scotland and Sweden may be referred to as proofs

The officers of Louthills have a regular library and reading society; and the works they make choice of are not only histories, voyages, travels, &c. but even works of taste, such as the British classics, and best novels and romances. The degree to which knowledge will prevail among any class of labouring men will depend chiefly on their own ambition, on the demand for knowledge, or the reputation in which it is held, and on the opportunities of acquiring it. A dull, stupid person, with little native activity, will never desire to learn more than what enables him to supply the ordinary wants of life; but where the necessities of any art are required to have technical knowledge of any particular kind, they will be found invariably to possess it. Thus carpenters and masons require some knowledge of the mechanical principles of architecture, and working engineers of the strength of materials; and these kinds of knowledge are acquired by them without an hour's interruption of their daily labour; on the contrary, the habit of evening study renders them more steady, active, and industrious than other workmen. Iron blacksmiths and paper hangers, for example, whose employments require much less intellectual skill. If every cool-smid, before she could obtain a first-rate place, were required to be able to read *Apicius* in the original tongue, there would be no want of learned cooks. And if no bailiff could obtain a first-rate situation who had not written a thesis in Greek, or who had not made the tour of Europe, there would soon be a great abundance of bailiffs so qualified. A Caledonian, when he comes to the low country, soon acquires the Scottish tongue, and he has been taught Latin, Greek knows three languages. The servants at the inn on some parts of the Continent, frequented by different nations, often acquire a moderate knowledge of three or four languages: a late custom-house officer on the island of Cronstadt spoke and wrote ten languages; and the bar maid at the hotel de Londres, at which we lodged in Moscow, in 1814, could make herself intelligible in Swedish, Russian, Polish, German, French, Italian, and English.

7064. The *curiousness of mankind* is to be increased with the necessity of possessing it, either to avoid the evil of being without it, or to satisfy the desires of others as to ourselves, or our own desires. There is scarcely any thing a rational man can desire that he may not obtain by maintaining on his mind a powerful impression of the necessity of obtaining it, pursuing the means of attainment with unceasing perseverance, and keeping alive that enthusiasm and ardour which always accompany powerful desires. All may not acquire, by the same degree of labour, the same degree of eminence; but any man, by labour may obtain a knowledge of all that is already known on any subject, and that degree of knowledge is respectable; what many never attain to, and what few go beyond.

7065. The *grand drawback to every kind of improvement*, is the vulgar and degrading idea that certain things are beyond our reach, whereas the truth is, every thing is attainable by the employment of means, and nothing, not even the knowledge of a common labourer without it. There are many things, which it is not desirable to dwell on, which are only desired by men of extraordinary mind; but let no man fancy any thing is impossible to him, for this is the base of all improvement. Let no young ploughman, therefore, who reads this, even if he can but barely read, imagine that he may not become eminent in any of the pursuits of life or departments of knowledge, much less in those of his profession: let him never lose sight of this principle—that to desire and apply is to attain, and that the attainment will be in proportion to the application.

## SECT. II. Professional Education of Agriculturists.

7066. In order that a professional man should excel as such, every other acquirement must be kept subservient to that of his profession. No branch of knowledge should be pursued to any extent that, either of itself, or by the habit of thinking to which it gives rise, tends to divert the mind from the pursuit of pursuit; something, it is true, is due to relaxation in every species of acquirement; but judicious relaxation only serves to whet the appetite for the vigorous pursuit of the main object. By the professional education of agriculturists, we mean that direction of their faculties by which they will first acquire the science and manual operations of agriculture, and we shall suppose agricultural pupils generally to have no other scholastic education than some knowledge of reading, writing, and arithmetic.

7067. All young men who intend embracing agriculture as a profession, whether as ploughmen, bailiffs, stewards, land-vaiuers, or rent-paying farmers, ought to undergo a course of manual labour for one year or more, in order to acquire the mechanism of all agricultural operations. When the pupil is not destined for any particular county then he should be sent to a farmer in a district of mixed agriculture; as, for example, East Lothian, where he would, if placed in a wheat and bean culture farm, see at no great distance the turnip system and feeding, and a few miles off, the mountain sheep-farming or breeding, when the pupil is intended to be settled in any particular county he ought to be sent to a county as near as possible of similar soil and climate, where the best practices are in use; as from all the turnip counties, pupils should go to Northumberland or Berwickshire; from the clay counties to East Lothian, or the Carre of Gower; from a mountainous district to the Cheviot hills, and Tweeddale, &c.

7068. The *term of apprenticeship* completed, the future time of the pupil ought to be regulated according to the ultimate object in view. If he is intended for a ploughman, shepherd or hedger perhaps to introduce new practices in other counties, he may remain for a year or two longer with other masters in the same district, in order not merely to acquire but to habituate himself to all the improved operations and practices. If he is intended for a bailiff, then after having been two years on one character of farm, let him engage for a second two years in a district of an opposite or at least of a different character; and for a third two years, on a third character. There are, as already shown, only three descriptions of farming in Britain; the bean and clover or clay land farming which includes feeding by selling; the turnip feeding, which includes feeding both by selling and pasturing; and the hill, or mountain, or pasture farming, which includes all the varieties of breeding. A young man therefore of ordinary intellect, who has worked two years in East Lothian on a clay farm, two years in the lower Berwickshire, or in the low part of Northumberland, and two years on the Northumbrian hills, must have a very competent knowledge of that part of agriculture known as farming or husbandry.

7069. The *higher branches of agriculture* or what may be called the engineering, valuing, and estate-agency departments, can only be completely acquired by first going through the course above described, in order to be bailiffs and common stewards, and next placing themselves under an eminent steward, land valuer, drafter, road engineer, irrigator, &c. as the case may be; making choice of a steward who has extensive woods and plantations, and also, if possible, some quarry, fabrication, or even mines under his care, and of a land valuer or drafter in full employment. When a solid foundation is laid by a thorough practical knowledge of all the operations of common agriculture, the higher part is attained with ease, and may be pursued with confidence; but, on the contrary when young men who know nothing of common country work are sent direct from school, or from an attorney's office to a land steward or agent, in order to acquire the art of managing landed estates, the worst consequences may be derived, both in the progress and the completion of the territory which may be subjected to them. The condition of many estates and tenants, managed by attorneys, may be referred to in proof of our assertion.

7070. Young men destined as rent-paying farmers after two years' labour as common servants, should be kept as constant bailiffs on other farms, till they are at least 25 years of age, no young man, in our opinion, ought to be put in a farm on his own account, or employed as a master bailiff, at an earlier period.

7071. In all cases when young men are destined for particular purposes they should be sent chiefly to particular districts; as, for example, young men intended for road-surveyors, to where roads are best managed, draughts to a draining country sent to Lancashire warpers to the Humber irrigators to South Essex, hedgers to Berwickshire, woodmen and foresters to Dumfries, or Blair in Athol, &c. If

would contribute much to the improvement of agriculture in the backward counties, if landed gentlemen would provide for their tenants to send their sons as apprentices, or even as ploughmen or farm-servants to the improved counties; or if lands brought up by the parish were sent there with a view to their acquiring the use of the improved implements.

726. *Whatever is the kind of professional knowledge to be acquired, the means of attainment is the pupil's paying such attention to what he sees and hears as to fix it in his memory.* One of the first things, therefore, that a young man should do is to cultivate the faculty of attention, which he may do every hour of the day, by first looking at an object and then shutting his eyes, and trying whether he recollects its magnitude, form, colour, &c. whether he would know it when he saw it again, and by what special mark or marks he would know it or describe it. When he goes from one part of the farm to another or is on a walk or journey let him pay that degree of attention to every thing he sees and hears, which will enable him to give some account of them when, returned from his walk or journey, and let him try next day or some days afterwards, if he can recollect what he had seen then, or at any particular time and place.

727. *The attention to be exercised in such a way as to improve the memory and enable the observer or hearer not only to recollect objects, but to describe them, must be exercised systematically.* A thing or a discourse must be attended to, not only as a whole, but as a composition of parts; and these parts must be considered not only as to their qualities of dimension, colour, consistency, &c. but as to their relative situation and position. To be able to give an account of a town or village, for example, the first thing is to get a general idea of the outline of its ground-plan which may be done by looking from a church tower or adjoining hill; next, its relative situation as surrounding objects, as what hills, or woods, or waters join it, and in what quarters; next, the direction of the leading street or streets must be noticed; then the intersecting or secondary streets, the principal public buildings, the principal private ones, where the lowest houses and narrowest streets are situated, and what is the character of the greatest number of houses composing the whole assemblage.

728. *To treasure up in the mind the characteristic marks of particular varieties and subvarieties of stock is a most important part of an agriculturist's professional education.* To do this effectively, some knowledge of sketching is of great use; and, if possible, ought to be acquired by every person intending to fill the situation of bailiff or steward. The knowledge of soils, plants, and their culture is a very simple business compared with the knowledge of stock, which is not only of difficult and tedious acquirement, but easily forgotten or lost for one gentleman's bailiff that knows any thing of stock there are at least a score that know nothing.

729. *In connection with professional studies, the pupil may find it necessary if his education has been neglected, to go on at his leisure hours with all the usual branches of education, either assisted by books alone, or by books and the best assistance he can procure.* If his school education has extended to arithmetic, mensuration, mathematics, and drawing he should occupy himself in acquiring a knowledge of botany, zoology, geology and mineralogy without a tolerable knowledge of each of which he will ever be in the dark among modern agriculturists, and in reading books on the subject. Next, let him study the various arts and manufactures that have any relation to agriculture, and store his mind with all he can acquire from one of the best general *Encyclopedias*, as that of Rees, or the *Encyclopedie Britannique*, with its excellent supplementary volumes. If he will go further and if he wishes to know the extent to which he may go, he may consult what we have advanced on the subject of education in the *Encyclopedie of Gardening*.

### BOOK III. Conduct and Economy of an Agriculturist's Life.

730. *A plan for the general conduct of life should be fixed on by every one when he arrives at manhood, not merely pursued for the time to come, most commonly such a plan is formed by the parents soon after the child's birth, and at the latest, when the boy is taken from school.* The boy arrived at manhood, however, is entitled to examine this plan, and amend it, or devise another more congenial to his own notions, but the risk of any change of this sort by persons so young and inexperienced is so great, that no youth ought to venture on it without the utmost consideration and the firmest persuasion in his own mind; where the parent has done his duty such changes of plan will not often be attempted; for by the early infusion into the mind of a child of ideas relative to the pursuit that is intended for him, a taste for that pursuit or employment will grow up with him, and become as it were his own natural inclination. This will happen in most cases, but in some children the bias or force of nature for some particular purpose is so strong, that by no parental instruction or reasoning can it be overcome; even where a sense of duty induced compliance with a parent's wishes for a time, the dormant inclination has at last broke out and taken the lead. In such cases, the parent may generally conclude, that where the pursuit or purpose is not bad, the force of natural inclination will be more likely to command success than the influence of parental authority, and that a pursuit or business, commonly of little profit or repute, will be more profitable and respectable when followed by a genius powerfully impelled to it, than a profitable and reputable business followed by any one against his inclination.

731. *The plan and conduct of life are in most cases determined by accidental circumstances.* The son of the labouring man grows up without any regular training or education for a particular end, and finds himself at the age of manhood engaged in rural labour and apparently incapable of any other. His notions and his ambition are so limited that he dare not venture to desire a change for the better, for no man ever desires that which he thinks it impossible to attain, and the mere idea of this impossibility however erroneous, effectually restrains the attempt at improvement. The life of the ploughman or labourer, much as it differs from that of a man of eminent natural powers and superior education, is capable of much amelioration by being directed to a suitable end or object as the ultimatum, or in other words, by proceeding on a plan. plan indeed, as we have elsewhere observed (*Encyc. of Gard.* 3d edit. 776.) is predestination, as conduct is fate.

732. *The greater part of mankind enter on life without any fixed plan or object in view or, if they have some general notion of acquiring wealth or distinction, they form no plan by which it is to be accomplished.* The consequence is, that such persons, after blundering on through their best years, arrive at the end without having gained any thing but experience, now of no use to them. No man is born in possession of the art of living, any more than of the art of agriculture; the one requires to be studied as well as the other and a man can no more expect permanent satisfaction from actions performed at random, than he can expect a good crop from seeds sown without due regard to soil and season. When we look round and observe the quantity of misery in the world, the greater proportion is, or seems to be, the result of a want of plan, or of a bad plan of life. How many persons are unsuccessful in their struggles to maintain a large family, the result of too early marriages: how many find themselves at old age with no other resource for support but charity: the consequences of want of foresight in expenditure: how many are suffering under poverty brought on by their own want of frugality, or positive extravagance; or under disease from excesses and irregularities committed in the heyday of life: and how many among themselves here to inherit property, who, at no period of their life, have any other alternative between hard labour and deficient food, than disease and want!

733. *Want of plan may not in every case be the cause of all this misery because accident enters into life for something both on the unfavourable as well as the favourable side of the question; but we have no hesitation in asserting, that want of plan, as a cause of misery is as ninety-nine to a hundred: any plan at all, even a bad plan is better than none; because those who set out on any plan with, in all probability sooner discover its errors if a bad one and correct them, than those who set out on no plan will.*

discover the want of *one* and form a good plan. The young man who is just setting out in life may well marvel at the contentment of peasants upon the journey without the guide of a postboy's plan; this plan he must form himself, because he alone feels what he wants, and what he can do to gratify them; all that we can do is to offer a few hints.

7751. In order to be able to form a plan it is previously necessary to determine the object to be attained by it. Happiness is the object of every action of human life, and consists in the gratification of certain wants and desires: some of these desiderata are peculiar to youth, and others to old age; but money, or clothing, food, rest, relaxation, entertainment, &c., begin with the earliest, and continue to the latest period of life. All these gratifications are procured by labour; in savage life, by hunting, fishing, and gathering fruits, till the man, no longer possessing strength enough for these labours, is obliged as he grows old and feeble to want; in civilized society they are also obtained by labour; but here what is called property exists, and man, in the leisure of his days, when the supplies of his labour are greater than the demands of his wants and desires, or when he chooses not to gratify the latter to the full extent admitted by the former, can, as it were, embody a part of his labour to be made use of when he is no longer able to perform it with ease: a man in this case is said to arrive at independence, instead of want, as in the case of the peasant, or of beggary, as in the case of the improvident.

7752. Independence is the grand object which every man destined to live by the exercise of his labour or talents ought to have in view. At certain periods of life, when the imagination is vivid, and bold and animated spirits in their utmost vigour, some may prefer present enjoyment, more sensual gratifications, or imaginary distinctions, empty conquests, titles, rank, military glory, and high literary or professional reputations. It is a noble attribute of our nature to prefer some of these to the mere accumulation of money; but a great warrior poet, or painter arrived at old age and want, if the latter be brought on by excessive improvidence, will not so himself remember by many means of distinction; and though it may possibly be some consolation to him that the three or four letters composing his name will be sometimes pronounced together after he is dead, yet it will not be much.

7753. The exercise of his profession is the most rational mode in which an agriculturist, of whatever grade, can procure independence. Only extraordinary circumstances can justify a change of profession; in common cases it indicates a want of steadiness of character or a want of success, and the latter is commonly attributed to want of skill. It is better therefore, to pursue unrelentingly the profession to which we have been educated, even though we should not be very successful in it, than to risk an infringement on character by adopting another. The practice of agriculture, as we have already seen, (7710.) is carried on by three different classes, serving, commercial, and artist agriculturists; on each of these classes we submit a few hints to aid them in forming a plan of life, and regulating their expectations.

7754. The greater number of agriculturists must ever belong to the lower grades of the serving class; and not as ploughmen, husbandmen, shepherds, hedgers, woodmen, and labourers of all-work. These form the greater proportion of mankind in every civilized country and must ever remain the bulk of material in the social fabric. Comparing one age and country with another, however, there may be the greatest difference in their intellectual and physical condition. The ploughman of Russia is but a remove from his horse. The ploughmen in different parts of Britain are as intelligent as their employers. In Scotland they have the Bible by heart; are familiar with the history of their country, and not ignorant of its literature; they lead a laborious life, but they enjoy the inestimable blessings of health, sound sleep, and peace of mind, till the latest period; they are almost always independent, either from their labour, their savings, or in old age or sickness, from the assistance they receive of their children in return for what was laid out on their education. These men are as happy relatively to their capacity for happiness as any other class whatever. If their measure is contentment, it is as full as the largest; for the elements of comfort and happiness are the same in all classes, and in all classes a man's wants and wishes accommodate themselves to the means of gratifying them. The rich have no wants, and their desires for the most part are no sooner expressed than gratified; the pains and pleasures of life are neutralized into a kind of insipidity till ennui brings on disease, which to this class becomes a blessing, by preventing for them the occupation of taking medicine, the duty of attending to the doctor's regulations, and the pleasures of convalescence.

7755. Contented labour even that of the humblest description in the country when it is not oppressive and where it is accompanied with abundance of food, sufficient clothing, and good health, is by no means inconsistent with happiness. It is a common but most erroneous idea, that happiness is confined either to the rich or the independent. Health and activity are the weeds, and a rich man who has nothing to do is unquestionably more miserable than any ploughman in the empire. "Happiness," says one who has thought much on the subject, "is the full and vivid satisfaction of the mind; and if content in content and unobtrusive enjoyment, that is, enjoyment not injurious either to oneself or to any other. Among the very first requisites to this satisfaction it will readily be perceived is employment, either bodily or mental, and the more energetic, without exhaustion, is the employment, the more full and vivid will be the satisfaction. The human mind is naturally active and, except in sleep, if even then, cannot with impunity be motionless or torpid. Occupation is as necessary to its health as circulation of the blood is to the body. Employed it must be, to know content or feel enjoyment; for by any want productive of pain, either bodily or mental, especially the latter, content and enjoyment are, according to the degree of the pain, destroyed or diminished; and the want, which the unemployed mind invariably feels, is as invariably productive of uneasiness, or bitterness, or lassitude, and their inseparable attendant, mental pain. Indeed this pain is, not unfrequently altogether unendurable. All the temper, kindness and propriety of business, says Dr Johnson, "are trifles and luxury compared with the insupportable variety of vacancy and the unsatisfactory expedients of idleness." "It is this intolerable variety of mind," says Paley "which carries the rich and great to the race-course and the gaming-table. It is this vacancy says experience, which often arms them against themselves, and hurries them to self destruction. If, also, unemployment is necessary to the health of the mind, exercise is to that of the body. Employment to the mind and exercise to the body are in some degree substitutes for each other; but, for the full content and enjoyment which constitute happiness, they both, in due proportion, are necessary" (*On comparative Manners*, vol. i. p. 6).

7756. The plan of life suitable for the operative agriculturist may very well be founded on the condition of the class of men in the northern counties of Northumberland, Warwickshire, East Lothian, and others. We have already (7734. and 7735.) described in general terms the manner in which farm servants are hired, fed, clothed, and paid in these counties; and detail by an eminent Northumberland farmer will be found in the sixth volume of the *Gardener's Magazine* (p. 682). The essence of the mode consists in the employer providing the employed with comfortable cottages and gardens, and paying them chiefly in the necessities of life, in so much meal or flour, so much ground to grow potatoes and flax or hemp, a cow's keep, the run of a pig, if a shepherd so much wool or so many sheep, the loan of a team to bring home coal or other fuel, and a certain proportion of money. By this mode of payment the operative agriculturist is always sure of a comfortable home and food, care of wife, children, wool, and potatoes, the produce of a pig, poultry and hens, and of the produce of his garden; and this, however high may be the price of these articles in the public market. These good things can only be rendered nugatory by the evil of a bad wife. All country servants hired by the year might be accommodated and paid more or less in this manner; and to this mode of life and payment they ought to look forward as the ultimatum of their grade in the scale of operative agriculturists. By prudent conduct, in regard to the interests of their family, and by frugality, they may live in decency and comfort, educate one or two children, and save something for old age, or unforeseen contingencies.

7063. The Northumberland ploughman is the happiest of labourers, and never feels a bad season. His wages are certain; and with frugality and care, his wife may bring up a large family upon this income. The reverse is sometimes the case; but this is attributed to a bad wife who wastes the produce of the cow. The small stock of the hind being always his own, and the cow generally so, makes him prudent and careful during single service to save as much of his wages as will set him up for himself. To this, and the fact that his wages of labour are never paid out of the poor's rate, the enviable state of the Northumbrian labourer is to be attributed. It appears to operate as a preventive check upon population, and beautifully illustrates Mr. Malthus's theory; or, in the words of Burns, it teaches them to "know that prudent cautious self-control is wisdom's root." They are all anxious to give their children such education as they can command. When they are within the reach of a charity-school they thankfully avail themselves of it, and we find in every hamlet some person who teaches the younger children the rudiments and several of these, when they get older, work and save the wages of summer to pay for getting themselves to schools in winter. (C. in *Gard. Mag.* vol. vi. p. 551. See also *Dominie's Farmer's Friend*.)

7064. The day labourer who has no particular employer and probably no fixed residence, is much less comfortable than the yearly servant in England, more especially, under the present system of poor laws and parish management, which is calculated to degrade him, and effectually to prevent any attempt at improving his condition. If, as Stanley observes, "by unregulated industry, he has been enabled to do without parochial relief" and bring up his children decently it is as much as could be expected for an attack of illness, or the temporary loss of employment, he is in general totally unprepared. He thinks not much of the morrow and, as it stands, it is perhaps well for him that he does not anticipate evils which he cannot prevent. Every one knows how beneficial to the community how advantageous to the individual, the hope of bettering his condition in life is. It cheers him in adversity, encourages his industry, promotes his content, yet from this hope the under part of the agricultural labourers of England are excluded; they toil indeed, but it is to continue not to better their existence." (*Essay on the Social Direction of Rural Expenditure*, p. 170. see also the succeeding chapters of those judicious and intelligent essays.)

7065. The condition of the labouring classes has lately been considered by the editor of the *Scottman*, in an article in his xvth volume (Nos. 1131 and 1132), which is also published separately in a tract entitled *The Scottman's Advice to the Labouring Classes*. The condition of the labouring classes, it is observed in this tract, may be deteriorated in two ways, "by increasing their numbers too rapidly and by diminishing the capital which provides them with employment. Now capital is either diminished, or its natural growth is impeded, by the enormous sums paid to the government, by the tax on corn imposed for the benefit of the aristocracy and by the many absurd restrictions on industry which have arisen from the ignorance or misapprehensions of our legislators. To repeal or relax these laws, to relieve industry from the restrictions which fetter it, benefits the working classes by enlarging the fund which creates a demand for their labour. The sufferings of these classes are therefore in no small extent, imputable to the excisions and misconduct of the government. Culpable and injurious, however as the extravagance of the government has been, I am convinced that were all the public burdens annihilated, and all the obstacles to freedom of industry removed, the relief given would be but temporary. The misery of the working classes must be mitigated by such means but it cannot be eradicated by legislation, nor by any human means except such as shall put some check on the increase of their numbers. Scientific thinkers regard this conclusion as established on the clearest evidence how then is the principle of increase to be checked? Only in one way by enlightening the minds of the working classes by inspiring them with feelings of self-respect; by teaching them the immense importance of habits of prudence, forethought, and self-control to their own happiness; by giving them true notions of their station as moral agents responsible for the consequences of their acts, and endowed with powers which if rightly used, would make them to a great extent masters of their own destiny.

7066. A radical view on human conduct, is that "in the article of marriage men consider life as a lottery and they rush into the most important of all ties, without making any provision for discharging the obligations it lays upon them. This applies to the middle ranks as well as to the lower." "Thousands and tens of thousands marry every year whose extraneous hands suffice for their own subsistence and multitudes throw their offspring on the world "with as little rational consideration about its future well-being, as the crocodile shows when she drops her egg in the sand, and leaves it to the sun and the winds to hatch her young into life." Such persons cherish their thoughtless conduct under the plea of trusting to Providence, but what is trusting to Providence but trusting to chance? Nature has endowed us with reason to regulate our conduct, and in most of the common concerns of life has enabled us to foresee the consequences of our acts. After making all the use of our reason that we can, enough will still be left for chance, which may turn out, as every day shows, as much against us as for us. "To neglect the admonitions of reason, and then trust to Providence to free us from the evils induced by our own thoughtlessness, is to call upon the Deity to work a miracle in our favour; and this, instead of promoting our improvement, is only to harden us in our folly."

7067. There are two traits of sad importance to the well-being of the labouring classes; the first is, that as no efforts of legislation can lift them out of their misery, their happiness must always depend on their own habits of prudence, forethought, and self-control. The second is, that no man has a right to bring human beings into the world, who is not able to provide for their support and education. The law punishes severely the act of exposing a child; but the man who marries and becomes the father of children, without having any reasonable prospect of being able to keep them from beggary with all its attendant miseries, is guilty of the same crime in a lower degree.

7068. To convert the burthen which marriage brings with it into money the *Scottman* suggests the following scheme he takes the case of an industrious mechanic beginning to earn 16s per week at the age of eighteen, and he shows what he could accomplish by living economically and deferring marriage till he was twenty-eight; he supposes him able to live upon 12s. 6d. per week, and to place 2s. 6d. per week in a savings' bank, by which his stock, including interest, will amount in ten years to about 100. At his marriage he is supposed to spend 50s. of this 100 in furnishing a house, &c. and to dispose of the remaining 50s. to provide against the following casualties.

7069. The first casualty after marriage which he has to provide against is sickness, which may be done by a weekly contribution of 4d. for himself and his wife.

7070. The second casualty is the infirmity of old age. This is to be provided against by an annuity from government, or a benevolent society; and 17s. 1s. 6d. or an annual payment of 5s. 6d. by a man at the age of twenty-eight, will obtain an annuity for him of 50s. per annum for whatever number of years he may live beyond the age of sixty-eight.

7071. The third casualty to be provided for is the possible widowhood of his wife this he may do by paying down 20s. 12s. for which a man of twenty-eight may secure for his wife, supposing her age to be the same, an annuity of 12s. for life, in the event of her being left a widow at whatever period it may happen. On this subject the benevolent and philosophical author of the scheme observes, "When society is more enlightened, it appears to me that a provision against the chance of widowhood will be considered as indispensable at marriage as a suit of wedding clothes.

7072. The fourth casualty is the chance of the death of the father before his child is able to shift for itself; that is, before it is fifteen or sixteen years of age. To ensure such child against this casualty, it is proposed to secure a small annuity to it in the event of his death, of say 5s. per week, up to its following year. Thus, the father being aged thirty, he calculates may be purchased for 5s. paid down the first year of the child's life. "A similar deposit of 5s. would be requisite at each addition made to the family; and as a marriage is assumed to produce on an average four children the whole sum expended under this head would be 20s. Those who have more than four children must make extraordinary exertions.

7972. A reasonable degree of security against the casualties of life may be afforded to a working man about to enter into the married state and his family for the sum of 100*l.*, which it is shown he might save by the age of twenty-eight. That sum would be disposed of thus:

Fortieths, exclusive of what was provided by the wife	£300
Anticipated himself in old age of 52 <i>l.</i> per annum	17
Assured of 3 <i>l.</i> per annum for his widow	20
Provision for four children	50
	£407

Therefore, let us men whatever, not even the most humble country labourer, think of marrying before he has saved 100*l.*; and let him beware of spending any part of this sum, even that part which is allotted for his family, but let him provide for the four casualties of the married state.

7974. To carry this scheme into effect, mutual assurance societies by the working classes themselves, or benefit societies, would probably be the best mode, and government and the more wealthy members of society ought to lend no time in assisting in their formation. It is justly observed, however, that it cannot be too often inculcated upon the working classes, that the improvement of their condition must be their own work. When this scheme carried into practice, it would diminish their numbers relatively to capital, and as a consequence, their wages would rise. Secondly, it would rescue them and their families from extreme poverty, give them independence of character secure to all of them the advantages of education, and thus break down the barrier which confines them to the sphere they are born in, and precludes them from obtaining any of the higher prizes in the lottery of life. To society the system would be equally beneficial, poor's schools, with all the abuses they contain, would be done away; crimes would be rare when pauperism was eradicated, and by the universal diffusion of education, all the talent in society would be made available. And last, not least, when every grown-up man had either a small stock of savings in hand, or investments in a common fund, we should have the very best guarantee for the public tranquillity. Did the working classes fully understand this scheme," its excellent author continues, "some basis of all the poverty misery, and crime which we see around us would disappear; we should in fact find ourselves in a new world, full of intelligence, peace, and good order, in which life and property would be ten times more secure, happiness more equally distributed, and an admirable foundation laid for the further amelioration of the lot of mankind." (Scottsman, Nov. 15, 1830.)

7975. The plan of life for the director class of agriculturists need hardly be pointed out; the rise from a farm bailiff to a steward's hall, or to a domestic bailiff or steward, and thence to the general steward or factor of an estate, is an obvious path of ambition. In another direction he may rise through the office of assistant gradations of the commercial agriculturist, or, adopting the rank of counsellor or artist, he may become a millman, appraiser, timber or land-surveyor, land-valuer, agent, or agricultural engineer; rarely however, can he attain the veterinary profession, or that of draftsman, author, or professor.

7976. The remuneration to which a director agriculturist is naturally entitled, should be regulated by his professional abilities and experience; that which he will commonly receive will be regulated by the quantity of agricultural talent and experience in the market. It ought always to be such as will render it worth his while to be honest, sedulously attentive to the interest of his employer, and of police and obliging manners. A handsome salary to such a servant is wise economy.

7977. The object of the artist or counsellor agriculturist may be either to ascend to the rank of author or professor, conditions of more honour than profit; or to realise property and become a proprietor cultivator. But a well-paying farmer, no artist or author is at all adapted.

7978. The legitimate object of a commercial agriculturist is to rise in the different grades of his class, and become either a large farmer, a gentleman farmer, or best of all, a proprietor outcultur.

7979. The profits to which a commercial agriculturist is entitled, comparatively with those of other commercial men, are theoretically determinable by the risk attending the employment of his capital, and the skill requisite to prosecute his art. But, practically this remuneration will depend on the quantity of skill and commanding capital employed in the culture of the useful products of the soil. It is evidently less than the risk of capital employed in many or perhaps most manufactures; and the skill requisite to enable any one to become a farmer according to the customary practices of the country surrounding him, is less than that required for almost any branch of manufactures. In consequence of these things, there are men every where ready to become farmers; hence the profits of farming are naturally less than those of most other pursuits. But, to counterbalance this, the farmer has several advantages peculiar to his profession. First, the nature of his residence in the country which secures a certain degree of consequence from its connection with a considerable group of out-offices, surrounded by a garden, orchard, fields, woods, and other rural scenery all in his occupation, and inhabited by servants in cottages, horses, cattle, sheep, and other domestic animals, in subjection to him, gives him a degree of consequence both real and apparent, and assimilates him more nearly to a lord of the soil, and to the possessor of that sort of rural retirement and independence which is the object of almost every commercial man's ambition, than any other mode of life could do. Secondly many trades and professions preclude (according to general prejudices) their followers from being gentlemen whereas, though every farmer is not a gentleman, yet any gentleman may become a farmer without in any degree lowering his rank and character. A farmer may, therefore, if he chooses to adopt the habits and manners of a gentleman, be reckoned as such. Thirdly, the farmer's products are in universal demand, and he is sure of a market of some considerable size, a fact otherwise with many manufactures. Fourthly he is sure of a home, of the necessities of life, and, in general, of most vigorous health. Fifthly he is generally a man of more personal influence than the tradesman or manufacturer.

7980. Scarcely any farmer makes a fortune by his profession; the utmost exertions of the most skilful and industrious men, in the most improved districts, seldom do more than enable them to keep pace with the times; and the great majority in all countries, lead a life of great labour and anxiety and end as they began. No farmer, in a general way, can raise more than one corn crop in a year and in this respect the farmer of Russia and Poland has the advantage of the British farmer; for the lands of the former being from five to eight months under snow, all root-weeds are destroyed, and the ground so loosened by the frost and thaw, as to require very little stirring for the seed. The ripe summer which succeeds ripens all annual plants that will grow there, nearly as well as in England, and better than in many parts of Scotland and Ireland. The British farmer, however, has the great advantage of a perennial pasture, owing to the mildness of our winters; but still no art of man will shorten the period of annual production, and originate a lamb or a calf in shorter periods than five months and forty weeks. How often does the tradesman or manufacturer turn his capital in that time! There are three varieties of professional farmers, however, who occasionally realise some property: the grazer who feeds with oil-cake, grain, and other artificial foods; the dealer in corn or cattle, who has the art to buy at a falling and sell at a rising market; and the dealer or broker in farms, who buys or sells his lease, or in portions of land, who subdivides and subdivides. The profits of the first are not great, and those of the last two are attended with great risk. The only farmer whose lot is to be envied, lives under a landlord who does not take the full marketable price for his lands; such as Burdett, Coke, Bedard, Northumberland, and many others in the north; but few in the north, or in the west.

Our notices under each month extend only to a few of the leading features of country-work — to attempt to insert every thing, or even most of the things that require attending to, we conceive impossible and, if it could be done, quite useless. A man will always act better when guided by his own judgment, than when following implicitly that of another. Calendars should only be considered as remembrancers, never as directives.

**JANUARY**

Thank you for the call, and the very  
firm hold through the company's hands,  
without the fact of the company's hands,  
and the fact of the company's hands.

**Grass (5005.)** are in some dry situations planted in the last week of the month, and the best and most successful crops are sown. On the other hand, it is better to defer the sowing until the first of February, and the soil will then be just what is required.

**Grass seeds of the common kind (5005.)** may be sown where the soil is suitable.

**7 Fences (5005.), Roads (5005.), and Drains (5005.)**

**Grass** may be planted in situations, in any of the following species (5005.) *Grass*, with, perhaps, and all other kinds of the common kind may be sown; but none where the soil is so dry as to be unsuitable. **Grass** by the different species (5005.) *Grass* and *Grass* may be sown in all these and others.

**3. Orchards (5075.) and Hop-grounds (5007.)**  
**Grass** and **Grass** may be sown in the last week of the month, and the best and most successful crops are sown. On the other hand, it is better to defer the sowing until the first of February, and the soil will then be just what is required.

**3. Wood-lands and Plantations (5005.)**  
**Grass** may be sown in the last week of the month, and the best and most successful crops are sown. On the other hand, it is better to defer the sowing until the first of February, and the soil will then be just what is required.

**Grass** may be sown in the last week of the month, and the best and most successful crops are sown. On the other hand, it is better to defer the sowing until the first of February, and the soil will then be just what is required.

## FEBRUARY

Weather at	Average of the Temperature	Quantity of Rain	Average of the Rainfall	Quantity of Rain	REMARKS.
London	52 2	3	50 24	0.575 inch.	This month (the spring or great fish month of the month) is usually subject to much rain or snow; which is not unusual considering the old proverbial saying, "February all day with either kind of weather." <b>Grass</b> (5005.) may be sown in the last week of the month, and the best and most successful crops are sown. On the other hand, it is better to defer the sowing until the first of February, and the soil will then be just what is required.
Manchester	52 10	3	50 24	1.250

## MARCH

Weather at	Average of the Temperature	Quantity of Rain	Average of the Rainfall	Quantity of Rain	REMARKS.
London	52 2	4	50 24	0.575 inch.	The beginning of March usually concludes the winter; and the end of the month is generally indicative of the season's going; according to the proverb, "March comes in like a lion, and goes out like a lamb." <b>Grass</b> (5005.) may be sown in the last week of the month, and the best and most successful crops are sown. On the other hand, it is better to defer the sowing until the first of February, and the soil will then be just what is required.

## 1424

## 2. Orchards (1979) and Non-orchards (1982)

This is the chief season for sowing wheat, rye, and flax, and for sowing different sorts of grass, clover, and other crops of pasture. It is also the season for sowing different sorts of fruit trees, and for sowing different sorts of seeds, and for sowing different sorts of plants. It is also the season for sowing different sorts of seeds, and for sowing different sorts of plants. It is also the season for sowing different sorts of seeds, and for sowing different sorts of plants.

clothes, socks for washing, etc., this laundry work not being your vice. (2nd.) Washes for picking and hair than the first wash. (3rd.)

*Shampooing and drying.* In the district where this work is much practiced, is the great business of the month. (4th.)

**3. Wood-lands and Plantations (306.)**

Routine operations on the two or three preceding months find everywhere during the three last weeks, and sometimes from the last day. (203.)

## OCTOBER

Weather at	Average of the Thermometer	Greatest Variation from the Average	Average of the Barometer.	Quantity of Rain.	REMARKS.
London	59 51	4	30 00	3.047 Inch.	The weather of this month is very uncertain. Several
Edinburgh	49 7		30 53	3.234	thunder storms, snows, or frosts which sometimes the present
Dublin	51		30 78	2.796	commencement of winter, there is generally less or more
					than these winds are common. The weather of the month
					was in October sometimes partly in November. These
					weeks often. Last measures for bringing forward the
					seasonal operations.

**REMARKS.**  
The weather of this month is very uncertain. Before these rains, snows, or frosts which sometimes the general commencement of winter, there is generally two or three weeks of settled weather, sometimes these weeks are in October sometimes partly in November. These weeks afford last resources for bringing forward neglected operations.

**Hay porridge.** A mixture of oatmeal and water, or any other meal and water left till it becomes sour, as practiced by the farmers in the northern section, will feed hogs readily. Wet milk and peas meal make the finest pork in the world. The leaves which have been used during summer may now be put on hay stacks and carrots, or other roots, by day.

In the first week the red wing (*Thalassidroma*) arrives. Swallows and vireos bury themselves in mud. Hooded mews (*Larus*), and wood-pigeons (*Columba*) arrive. House martins (*Fringilla*) congregate, and prepare for migration, leaving their nests in this country.

**Third week** the snipe (*Scolopax gallinago*) appears in the meadows. Wild-geese (*Anas grysbach*) leave the fens, and go to the fly-lands.

4. Great Lakes (E842)

In the first week of the Chinese New Year, strawberry tree (*Adiantum species*), belly (First Adiantum), China hollyhock (*Alcea chinensis*) and China rose (*A star chinensis*), in bloom.

Saved seedlings of some species of *Meier* turned, leaves of the sap almost all off. The *Meier* chinensis, yellow; of the sugar maple (*Acer saccharinum*) purple; and of the common birch yellow and gold and of the weeping birch, gold and

Third week: Cylindrical catkins in flower. Some horse-chest  
nuts and hawthorn grove bordered of leaves.

Fourth, most warm plants, especially annuals, come in a flower. Leaves of warm-plant (*Struthium* & *Struthium*), of blue pink; of single-blossomed, of purplish red of the American side, of blue shades of yellow orange, red, and

Where they are required, the

This is the season of rural plenty offering an opportunity both to man and animal, for laying in large stock of health to enable them to support the severity of the coming winter. (poultry) could now buy in their winter stores of potatoes, feed, etc. and range up their garden ground, not under crop.

[illegible]

Michigan is also the general term for hiring farm-servants by the year; but the southern agricultural operatives are changed the better, unless in the case of slaves, indentured, or viciously inclined persons, who degenerate when frequently removed.

operation (578K); choose dry weather.

Cables and slings not sufficiently fitted on grain or lumps, whether by passage or rolling, should now be put on a surface, to complete them for the lumps. Oil-cake, gravel, turpentine, concrete, or in default of these, brushed down may be used. The same observations may be applied to hops, which are usually in great quantities at this season. (725A)

## 4. Arable Lands. (4025)

NOV 1964

potatoes (5291) carrots (5445) field peas (5492), turnips (5471) and Swedish turnips, may now be taken up and loaded, and the ground sown with wheat. This is in (5001) rye (5082) barley (5080.) in some situations, and turn (5287)

may still be seen in the arid districts. Immature swallows apparently to give the first swallow to farmers (1964), whereas the young are given eggs or other swallows in general all lands that are to be given trees or some farrow before they are seen or planted. They should be placed as soon as possible after harvest but not in fields that are to be used on one field which are better in the fields of the winter and February. It is a common practice to place the young in a small ditch on the eggs or in a small ditch of land (1965), or the small of water on the country. It may also, by giving them deeper coverage, preserve them from the winter's frost, or what is much more so destructive from being consumed by birds. These are few subjects have been understood from the economy of nature.

7. *Busset* (2060.1), *Book* (3523.1), and *Dress*

(4211)

Hedge may now be advantageously planted (1978), as growth has been rapid since 1967, old ones reaching 20-25 m tall and 10-15 cm diameter (1968). The Northernland practice is to plant hedges (1968), well deserves the study of the more southern practitioners. Roads and dunes may be made or repaired at any season, and in winter, with better effect than during the heat and drought of summer. Road materials now being better and heavier, their strength more satisfactory.

B. Orchards (4079) and Non-orchards (5007)

The tender fruits may now be gathered, and either spread in an airy loft, or tapers fixed there to remain till used, or sweated in heaps, to extract a part of their moisture, and then buried in dry sand, or packed in close trunks or casks, to be kept in a cool and dry cellar (1834. and *Tracts of Gardening*, 2d Edition 1839).

Fronds trees of every kind may now be planted (4105.) and

Deep-plowing is generally completed the first week of the month and in most afterwards is convenient, the vine and weeds removed, and the latter plowed till just before. (1947.) Young hop plantations may be formed (1948.) and the soil strongly established grounds secured and ploughed. (1949.)

9. *Wood-jacks and Plantations.* (2006.)

Edgemoor and plantations of cypress from May to June during the first week of the month; and no part of the year is better for transplanting all kinds of hardy plants.

These and copies may be sold, and in general every operation proprietary in planting, as well as the operation itself may be insured.

**NOVEMBER**

REMARKS.				
Weather in	Average of the Thermometer	Greatest Variation from the Average	Average of the Barometer	Quantity of Rain.
London Bathurst Dahlab	44 44 41 41 45	4	29 95 29 926 29 74	2.007 inch. 4.015 0.094

This is the whole work of the Ganges; it is generally also cold and muddy, and one of the great disadvantages for the laboring population; but he never fails to be aided with the assistance of the fish, and takes the opportunity of evening, when he may lay aside his wet dress and finally be joined by showers with tepid, to make the comfort of his fire-side, and the witness of his wife and children; content to sit otherwise depending upon a number of his family or those.

# GLOSSARIAL INDEX.

\*P In this Index both Pages and Paragraphs are referred to; the letter p. is prefixed to the former to the latter the letter a.

**ABRADING** earth, earth crumbling down from the effects of frost, page 483.  
**Absorbent soil**, soil so constituted as to absorb moisture from the atmosphere, 772.  
**Absorbent system**, explained in a. 6382. p. 268.  
**Acclimating** vegetables or animals, inducing them to a climate in which they are not indigenous. The term naturalizing is sometimes substituted, but erroneously. See *Naturalizing*.  
**Account**, entering a state of acid fermentation, a. 6374. p. 1034.  
**Airstrat**, exposing the soil to the air. p. 507.  
**Aërometer** leads hollow beads of glass containing air for ascertaining the specific gravity of milk, a. 7008. p. 1032.  
**After-grass** the second crop of grass from lands which have been previously mowed the same year, p. 905.  
**Aftermow**, the second mowing of perennial meadow lands in the same season, p. 815.  
**Aggriculture** is used in its most extensive sense in the third line of the title-page, and generally in the historical part of the work (Part I.) as including territorial economy and husbandry. In most parts of this work, for example, in the words of the title-page, "animal and vegetable productions of agriculture," as synonymous with husbandry. In several places as synonymous with aration that is, the culture of arable lands, as opposed to pasturage, or what may be called agriculture proper. In every case the reader will be able to gather from the scope of the sentence or paragraph containing this term, in which of these three senses it is meant to be understood.  
**Aggrivation**, tufts of fushers, p. 1066.  
**Ails** small islands, or islets in streams.  
**Alburnous parts**, soft woody parts, p. 681.  
**Alburnum**, the soft sappy wood just under the inner bark, p. 646. See *Leadley's Outline of the Principles of Botany* p. 17.  
**Alien waters**, a brook or stream passing from one area through another which has been embanked from a river or the sea, p. 715.  
**Allopathy** independently of any superior, p. 632.  
**Alluvial soil**, soil deposited by streams, p. 74.  
**Alvine purge**, a purge composed of the scoterine aloes, p. 1145.  
**Alternative** alternative medicines are those which induce a change in the blood and juices for the better without any manifest operation or evacuation, p. 877.  
**Alveolar sockets** sockets like the cells in a honey comb, p. 872.  
**Amalgam**, explained, a. 6695. p. 1002.  
**Amercement**, a pecuniary punishment arbitrarily imposed, p. 769.  
**Anomalous genus**, a. 6701.  
**Anomalous sterc**, without regular shape, a. 3005. p. 683.  
**Anthery**, an excrescence in some plants of the natural order Cruciferae, and chiefly in the turnip, produced by the puncture and depositing of the eggs of an insect, a. 6487. p. 881.  
**Antacid**, a chemical product obtained from plants, a. 1468.  
**Anastomosing**, irregular, p. 892.  
**Artery**, the great artery of the heart, p. 967.  
**Artes ascendens** the ascending great artery of the heart, p. 967.  
**Artes descendens**, the descending great artery of the heart, p. 967.  
**Asymet**, a reciprocal action between the mouth of the horse and the hand of the rider; the bit and rein forming the line of communication. Thus a

horse with a sensitive mouth has a good asymet, and the same may be said of the rider if his hand be good, a. 6863. p. 1002.  
**Aqueous humour** the watery humour of the eye; the first or external, and thickest of its three humours, p. 970.  
**Aratton**, ploughing or tillage, a. 2822. p. 873.  
**Arumense grasses** grasses suitable for sandy soils, p. 744.  
**Arvumensor**, a pruning instrument, consisting of two blades fixed on the end of a rod, acting like scissors, by means of a line fixed to one of them, and pulled by the operator a. 3125. p. 519.  
**Arms**, the boards or long bristles which project from the shaft they are plentiful on spring wheat, and on barley, p. 815.  
**Atmosphere** explained, a. 686. p. 807.  
**Auote**, the radical principle of the atmosphere air p. 814.

## B.

**Baching** a horse, explained, a. 6527. p. 1000.  
**Bact-raising**, an operation in surgery by which hardened faeces are withdrawn from the rectum, a. 6543. p. 990.  
**Bact-rents**, rents paid subsequently to reaping, p. 768.  
**Baggins** explained, a. 3173. p. 575.  
**Bails**, a substitute for fixed standings or stall dividers, a. 6722. p. 1008.  
**Bawl-ave ridges**, ridges formed of such a width as to be reaped by what in Scotland is called a band of shearer or reaper, a. 2550. p. 585.  
**Bawls** explained, a. 6382. p. 972.  
**Bastard-cocks**, small preparatory haycocks, a. 5797. p. 904.  
**Battering**, as applied to fences, leaning inward, a. 4604. p. 754.  
**Baulk**, in Scotland, ground left unturned between the furrows, alices in ploughing, p. 711. in England the same thing, and also strips of ground usually in grass between ploughed ridges, as in common field lands.  
**Bawns**, brush-suggets, a. 3555. p. 584.  
**Beet** an iron instrument used in the Isle of Ely to eradicate weeds in water-courses, a. 6595. p. 822.  
**Beds**, the dead stems of grass in pasture grounds which have borne seeds.  
**Beig** a variety of winter barley, a. 5083. p. 823.  
**Billet**, a term variously employed. A wooden billet is often used in docking a horse, and often forms a separation between carriage horses, a. 6733. p. 1004.  
**Binding and sheaving** binding sheaves of corn and placing them in sheaves or stacks, a. 3375. p. 518.  
**Boat**, a variety of double mould-boarded plough, a. 6840. p. 805.  
**Boat holding**, a mode of legal tenure in Scotland, a. 5401. p. 579.  
**Blaw**, a disease in the stomach of sheep and oxen from wind; also a term for the mildew in wheat, p. 1085.  
**Blending**, filling up interstices between stones on roads with gravel, &c. a. 6554. p. 689.  
**Blow down**, in horses, 501.  
**Blowing lands**, lands whose surface soil is so light as to be liable, when dry, to be blown away by the wind, p. 870.  
**Blowing sand**, p. 742. See *Blowing lands*.  
**Boles of trees**, the trunks of trees, p. 693.  
**Boll**, a measure for corn in Scotland, in wheat and beans, equivalent to four Winchester bushels; in oats, barley and potatoes, to six bushels, p. 642.  
**Bone spade**, explained, a. 6817. p. 883.  
**Booster stones**, large round stones, p. 643.

*End of the plough*, the going and returning with the plough along a land or ridge under ploughing, a 5892. p. 589.

*Eur drains*, explained, a 5891. p. 581.

*Eggs*, a vat or tub, a 7064. p. 1045.

*Everts*, from behind, to spring up, a 5897. p. 517.

*Evets*, a large barrow, a 5828. p. 608. In machinery a constraining wheel divided into joints, which stops when needed another wheel that revolves within it.

*Evitable dead*, heads made of the long shoots of the bramble or blackberry, a 5191. p. 518.

*Evings*, explained, a 7358. p. 1055.

*Evish-chure*, explained, a 7359, 7360. p. 1055.

*Eve using over a hedge*, cutting it down, p. 463.

*Eveches*, that part of the horse's harness attached to the saddle, and hooked on the shafts, which enables him to push back the cart or other machine to which he is harnessed.

*Evending on the line*, or in the same line explained, p. 501.

*Evending to and on*, explained, p. 501.

*Evending, cross*, explained, p. 501.

*Evender figure*, a quarter-of-a-rod, as thick as the finger and four feet in length, used in thatching, p. 518.

*Evess*, a Scotch dish made by pouring boiling water on oatmeal, and sometimes on the meal of peas, and some lately mixing them by stirring leaving the meal in small lumps or lumps about the size of marbles. It is afterwards eaten with milk or butter, a 5817. p. 537.

*Evagee holding*, explained, a 5404. p. 572.

*Evets, short angular ridges, short irregularly shaped lands or ridges in the corners of fields*, a 5265. p. 47.

*Evess, cross-shed*, a 5777. p. 1015.

## C

*Cadence* as applied to horsemanship, an equal measure or proportion observed by a horse in all his motions when he is thoroughly managed, and works justly at a gallop, *terma a terra*, so that his motions or turns have an equal repeat to each other, a 6572. p. 1003. See *Craig's Technological Dictionary*.

*Caesars* temporary chests in which foundations in deep water are built, a 4537. p. 718.

*Calcerous soil*, soil abounding with lime, p. 775.

*Calipers*, or calibers, explained, a 477. p. 654.

*Calorifer*, from *calor*, heat, and *ferre*, to bear explained, a 7464. p. 1077.

*Camping potatoes*, explained, a 5845. p. 851.

*Canon of the horse*, explained, a 6532. p. 858.

*Canter*, the predominant part of the saddle behind, a 6015. p. 1023.

*Capillaries*, the hair like extremities of the arteries and veins, a 6342. p. 933.

*Cap of straw*, explained, a 5110. p. 512.

*Caprodes*, leaps made in one and the same place without advancing forward, a 6528. p. 2428. See *Craig's Tech. Dict.*

*Capulet*, explained, a 6012. p. 937.

*Carotid arteries*, two principal arteries which carry the blood to the head, a 6506. p. 973.

*Carotids*, 971. See *Carotid arteries*.

*Carriage*, explained, a 6517. p. 955.

*Carriage in irrigation*, explained, a 4405. p. 795.

*Carve*, explained, a 4254. p. 747.

*Coronula lachrymatis*, explained, a 6370. p. 970.

*Cassens*, of the nature of cheese, a 6578. p. 1036.

*Castrate* to incapacitate male animals from engendering offspring, a 7306. p. 1029. See *Spay*.

*Catch-drain*, explained, a 5419. p. 737.

*Catch-work mechanism*, explained, a 4428. p. 737.

*Cannon*, a sort of case band, either of iron, leather or wood, fastened round the nose of a horse to forward the supplying and breaking of the horse, a 6597. p. 1001. See *Craig's Tech. Dict.*

*Caulicles*, an important membrane in animals in which the fat is lodged, p. 785.

*Cereal grasses* the kinds producing corn, p. 733.

*Cerebral lymphatics*, explained, a 7367. 7368. p. 1056.

*Cerebral Aqueduct*, an apertures or string passage of puriform, which runs along the neck and upholds the head, p. 772.

*Chamberlain*, a kind of long whip used in riding horses, a 6062. p. 1001.

*Cher wood*, so, to justify them it to enable it to resist wet, a 5125. p. 626.

*Charcoal*, the blackish substance, a solid species of the sweetest kind, p. 686.

*Chloride of calcium*, quicklime, a 4888. p. 519.

*Chyle*, a milky fluid secreted from the stomach in the lactal vessels.

*Clypeus*, that poulton-like mass to which the food is reduced in the stomach of every animal, a 6404. p. 578.

*Clothes*, to haul over with a snar, p. 512.

*Cuts*, explained, p. 570.

*Clothes*, explained, a 7392. p. 1055.

*Clothes*, cramps or holdfasts; to clinch, to turn the points of nails which have been driven, as in the shoeing of horses, a 6712. p. 2007.

*Cloths*, explained, a 6465. p. 738.

*Cob*, a kind of wicker basket, made so as to be carried on the arm, hence a seed-cob, or seed-lip, is a basket for sowing from, p. 578.

*Cocle cast*, a kind of kiln for drying hops upon, a 6045. p. 567.

*Coff*, a Cornish term for coffin pichards, p. 1172.

*Coffin bone*, a bone in the foot of the horse, a 6417. p. 576.

*Cohesive soil*, a soil whose parts stick together, p. 772.

*Collar-blade or Ancone* short segments of wood or metal, embracing the neck of the horse, to which the traces are attached, a 5238. p. 584.

*Collaps*, explained, a 7671. p. 1500.

*Commencement of tithes*, the substituting a fixed money payment, or a portion of land, instead of a tenth of the produce.

*Combs cartilages*, the gristles of the ear, a 6764. p. 1013.

*Condition of a horse*, the state of health and strength, p. 977.

*Concave following*, p. 525.

*Copphold*, explained, a 5306. p. 552.

*Cornic vesicles*, or chicken vesicles, tendons called into action by braying in the ass, a 6765. p. 1013.

*Cornua* the first or outer coat of the eye, a 6571. p. 970.

*Cornetts*, a mode of riding, a 6572. p. 1003.

*Corollary* a consequent truth gained from some preceding truth or demonstration, a 4961. p. 949.

*Coronal roots*, explained, a 4983. p. 918.

*Coronary*, explained, a 6117. p. 976.

*Cotyledon*, the first or seed leaf or seed lobe of a plant.

*Complex chains*, collars, or mechanical contrivances, by which dogs, &c. are coupled together.

*Cowries*, explained, a 5189. p. 518.

*Crest*, upper part of a hedge bank, p. 463.

*Croppers* a variety of pagot, p. 1056.

*Cross breeding*, explained, a 5023. p. 501.

*Crosses and furrow ploughing*, explained, a 3626. p. 547.

*Crows neck*, a disease in the horse, p. 1007.

*Crystalline humor*, explained, a 6574. p. 970.

*Culms*, stems of grasses, p. 1167.

*Cultivators crops*, crops of plants whose stems yield straw as wheat, barley &c., p. 788.

*Curb*, explained, a 5514. p. 982.

*Curt*, explained, a 5511. p. 984.

*Curling*, a kind of curled lines.

*Cut over*, to cut off the top crop, a 4043. p. 628.

*Cutting in horses*, explained, a 5899. p. 888.

*Cut water* of a bridge, the projecting part of the pier of a bridge, which is exposed to the current, and divides it, a 3512. p. 581.

## D

*Dandruff scurf*, a 6736. p. 1006.

*Dashing or dashed*. See *Lipped and harled*.

*Dead hedges* hedges made with the prunings of trees, or with the tops of old hedges which have been cut down.

*Dead timber*, any timber not growing, p. 808.

*Deciduous*, shedding the leaves in autumn.

*Decoritied*, deprived of the bark, p. 656.

*Deflection*, explained, a 4591. p. 837.

*Dendrometer* an implement invented to ascertain the quantity of timber in standing trees, p. 653.

*Deposition*, carrying away removal, p. 516.

*Draw-netting* spreading hemp or flax on grass to expose it to the action of the dew, which expedites the separation of the fibre from the scutid matter, a 304. p. 318.

*Devotions*, the name of a species of lunatics in Notinghamshire, a 6569. p. 627.

*Diagram*, an explanatory sketch, a 737.

*Diarrhoea*, explained, a 6573. p. 983.

*Diastole*, explained, a 6551. p. 986.

*Digging his toes*, in horses, explained, a 6598. p. 890.

*Dike*, explained, p. 695. In Cambridgeshire a ditch is called a dike.

*Dissecting plant*, a plant bearing its male blossoms on one plant and its female on another, a 3151 p. 617.  
*Dishevelled timber* timber deprived of its bark, a 4053 p. 823.  
*Dishes*, applied to a wheel, exploded, a 3702 p. 605.  
*Dishes*, in farming, hollow places in the fields, in which the water lies, p. 823.  
*Diuretics*, food or drink causing a copious discharge of urine, a 6410 p. 975.  
*Docking and nicking* cutting off part of a horse's tail, and cutting a notch or nick on the under side of what remains, for the alleged purpose of making him carry it well; now almost obsolete, a 6039 p. 1002.  
*Dome*, shaped like a dome or an arch, a 4507 p. 740.  
*Dorsal cervical joints* of the back bones, a 6704 p. 1013.  
*Double broaches*, broaches or splits are two-foot lengths of split hard branches, employed in thatching, p. 578.  
*Double round-rows*, double ranges of new-made hay, a 6797 p. 904.  
*Doves together* to join so closely as to form a smooth surface, a 3710 p. 602.  
*Dove shears*, breast ploughs to pare off the turf on downs, a 3215 p. 321.  
*Dragoon*, a variety of pigeon, p. 1095.  
*Drum mine*, explained, a 4406 p. 735.  
*Drum cut*, explained, a 3151 3162 p. 512.  
*Dronecarts*, the name of a four wheeled carriage in Russia, a 5 41 p. 1010.  
*Dry stone walls* built without mortar a common practice in stony countries, a 3065 p. 467.  
*Dwellhouse*, the first of the intestines, and connected with the stomach a 4406 p. 975.  
*Dwell*, a passage through which any thing is conducted.  
*Dynamometer*, or draught machine, explained, a 2 63-2563 p. 355.  

E

*Earth*, as applied to the surface of the globe, one or more of the earths, as loam, clay, sand, &c. in a friable or divided state, and either alone or mixed but without the addition of much organic matter.  
*Empysematous swellings* swellings filled with a windy humor, a 6044 p. 1005.  
*Enteritis* explained, a 6426 p. 892.  
*Ergot* of rye, spur of rye a disease in the kernels of that grain, p. 822.  
*Erucæ*, the larvæ state of insects, p. 1112.  
*Ete dry* an arm of the sea, the mouth of a lake or river in which the tide ebbs and flows, a 3495 p. 5 5.  
*Etiolated*, drawn out into a weak state, p. 808.  
*Eustachian tube*, explained, a 6385 p. 972.  
*Exoles* to unfold, disentangle, develop, or separate.  
*Eyes in plants* a bud.  
*Eyes in cheese*, explained, a 7067 p. 1045.  

F

*Fagel*, or shagreen, ass's skin, a 6757 p. 1012.  
*Fake ribs*, explained, a 6314 p. 904.  
*Fancy* explained, a 6495 p. 925.  
*Fanner* (from *faner* Fr.) farming agriculturist, farming cultivator professional farmer common dial farmer rent-paying farmer &c. a proprietor cultivating his own estate is not correctly speaking a farmer; to be such he must pay a rent. A proprietor who cultivates his own soil may be a gentleman or yeoman agriculturist or husbandman, a *proprietary cultivator*, but not a farmer.  
*Farmery* the household or farm-yard, p. 677.  
*Farming* renting land and cultivating it, or employing it for the purposes of husbandry.  
*Fanner boarding* sometimes called weather boarding, boarding, in which the edge of one board overlaps a small portion of the board next it.  
*Fecondity* of color the less or drought, p. 673.  
*Fer, fermhold*, explained, a 3804 p. 551.  
*Feeding pastures* pastures used for feeding stock, p. 903.  
*Felony*, explained, a 3351 p. 587.  
*Feline*, a disease in cattle, explained, a 6948 p. 1023.  
*Femur* the thigh bone p. 925.  
*Ferruginous water*, water impregnated with iron, p. 794.  
*Fish-baiting*, explained, a 3402 p. 522.  
*Fish a house*, to hold a house on a fish right, a 3921 p. 60.  
*Fishes*, explained, a 6237 p. 905.  
*Fleeces*, explained, a 7504 p. 1105.

*Fleeced*, explained, a 6778 p. 1015.  
*Fingers and toes* explained, p. 931.  
*Fishbait*, a variety of signet, p. 3428.  
*Flesh*, the second coat wool off *Martin sheep*, a 7142 p. 1032.  
*Fleet* of tares, a measure used in Scotland, in wheat and barley, equivalent to the English bushel, a 3222 p. 602.  
*Fleket*, knives or portable pales for fencing, a 3044 p. 453.  
*Fleeking* explained, a 5250 p. 518.  
*Fleeced cattle*, explained, a 6780 p. 1015.  
*Flight*. See *Chase*.  
*Flooders*, explained a 4448 p. 731.  
*Flow bag*, or flow more, a poet bag, the surface of which is liable to rise and fall with every increase or diminution of water, whether from rains or internal springs, a 3022 p. 555.  
*Flowering seedlings*, explained, a 4487 p. 747.  
*Fluke*, a disease in sheep, p. 1042.  
*Fluke worms* animals of the genus *Fasciola*, a 7371 p. 1006.  
*Fetus*, a young animal in the womb, p. 976.  
*Fogging pasture lands*, explained, a 3837 p. 908.  
*Foliage crops*, plants cultivated for their leaves to be used green, and which will not make into hay as the cabbage-tithe.  
*Foot rot*, explained, a 7303 p. 1006.  
*Forage plants*. See *Herbage plants*.  
*Forfeiture* rents paid previously to the first crop being reaped, p. 767.  
*Fort and caudex*, explained a 7137 p. 1008.  
*Forring* explained, a 7157 p. 1009.  
*Founder of the feet of horses*, explained, a 6517 p. 967.  
*Free martin*, explained, a 6894 p. 1021.  
*Frechold* explained, a 3203 p. 551.  
*Frit*, colic, gripes, or gallens.  
*Fruite sole* crumbling sole, p. 802.  
*Frondeux branched trees*, full of branches, which are flat and spread horizontally, like the fronds of ferns, as in the spruce fir, a 3387 p. 848.  
*Frontal suture* explained, a 7670 p. 1005.  
*Frustum*, a piece cut off from a regular figure, a 5 22 p. 606.  
*Furnished*, explained, a 6947 p. 955.  
*Fusiform root* shaped like a spindle, as the carrot, parsnep, &c. p. 845.

## G

*Gadon*, single shewen tied in a particular manner p. 514.  
*Gadling* explained, a 3176 p. 515.  
*Gauge courses or slips in thatching*, p. 518.  
*Gastric juice*, the juice of the stomach of any animal, p. 974.  
*Gaw furrows*, explained, a 4657 p. 803.  
*Girding anti-hills* explained, a 5775 p. 502.  
*Geon*, wild cherry a 3894 p. 590.  
*Gibbous*, protuberant, bearing excrescences, a 6775 p. 1014.  
*Gid*, explained, p. 1038.  
*Giear* the mucous evacuation in the scouring of horses a 6950.  
*Glanders*, explained, p. 885.  
*Glenoid* the hollow of socket in one bone at a joint which receives the knob, bone, or head of the approximated bone, p. 529.  
*Gluons* the husk or chaff of corn. Oat flights are the glumes of the oat, p. 868.  
*Glutra*, a tenacious, ductile, and elastic substance, forming a constituent part in wheat flour and other vegetable bodies, p. 771.  
*Go-downs* explained, a 6750 p. 1010.  
*Goggles*, explained, a 7387 p. 1050.  
*Grass-rocks*, hay-cocks, p. 504.  
*Gramen*, all the natural order of Gramineæ, of Lamnæ and Juncæ. Cereal grasses, those grown for bread corn. Pasture grasses, those grown chiefly for pasturage. Fumous or humifrons grasses, those grown chiefly for hay.  
*Grassing flax*, bleaching it on the ground, p. 515.  
*Grassie*, a disease in horses, explained, a 6514 6516 p. 967.  
*Gravel rot*, explained, a 7261 p. 1005.  
*Green acres*, land capable of 63 bags, p. 1305.  
*Grouting* filling up, a 3711 p. 602.  
*Gulds serina*, explained, a 6441 p. 860.  
*Gutter* a furrow-channel or drain, a 6613 p. 788.  
*Gypsum*, a genus of calcareous earth, consisting of a mass of bones and united with sulphuric acid. The principal species is the *Gypsum alabastrum*, plaster of Paris, or alabastrum. See *Crab's Trich. Dend.*

**Ho-ho**, a cork fence, p. 474.  
**Hocking and picking**, *see* *Picking*.  
**Holland's meeting**, explained, a 517A p. 515.  
**Hollowed**, a small shed, with a yard for feeding  
 one, or at most two animals, p. 468.  
**Hoofs of tobacco**, leaves tied up by their petioles,  
 so that the leaves spread out like the hand, a  
 504A p. 501.  
**Hoops, hoops**, a 504A p. 501.  
**Hooded**, a 507 *see* *Lined*.  
**Hook**, explained, a 573A p. 518.  
**Hooten, hood-gates**, p. 730.  
**Hooted out**, explained, a 7105 p. 1044.  
**Hoots, hoots**, a 5175 p. 518.  
**Hoots**, the base of the stalks or stems of all crops,  
 after the seeds are reaped or gathered. The  
 husks of peas is in some places called pea ryes.  
**Head and tail of gates**, explained, p. 500.  
**Heading down trees**, topping or cutting off the heads  
 of trees, p. 631.  
**Heading sheaves**, the head sheaf or sheaves of  
 sheafs of corn, p. 518.  
**Headland**, explained, a 4411 p. 738.  
**Headless**, iron combs, p. 525.  
**Headling, sea**, combed, p. 518.  
**Hebards**, a variety of pigeon, p. 1005.  
**Hepatic affection**, affection of the liver, p. 1037.  
**Herbage plants**, herbage plants, such as clover and  
 other plants cultivated chiefly for the herb, to be  
 used either green or made into hay.  
**Hides-bound**, a disease in horses and cattle when the  
 skin cleaves to the sides, a 6605 p. 977.  
**Hill**, explained, a 5171 p. 532.  
**Hilly**, explained, a 6705 p. 1015.  
**Hilts**, a Scotch term of the same meaning as the  
 English term "hilt," a 6705 p. 1017.  
**Horns**, thick scales, p. 772.  
**Holms**, small islands, but larger than sits.  
**Head-shed**, a shed placed on the summit of other  
 sheds for a covering, p. 515.  
**Hoot boxes**, boxes in the hind quarter of cattle, a  
 6705 p. 1015.  
**Horn's frog** of the horn, the prominence in the  
 hollow of a horse's foot, p. 976.  
**Horsemans**, a variety of pigeon, p. 1005.  
**Horser**, pieces of wood used in larking trees,  
 p. 631.  
**Hos for**, explained, a 5005 p. 504.  
**Hos peltum**, explained, a 7251 p. 1065.  
**Hose**, explained, a 7254 p. 1065.  
**Hosshunt**, a kind of clock, a 5533 p. 917.  
**Hossons**, the arm bone, p. 525.  
**Hosshunt machine**, explained, p. 440.  
**Hosser's rat**, explained, a 7304 p. 1008.  
**Hosser's rat**, horses soil feeding much manure,  
 p. 772.  
**Hosshuntman**, one who farms generally that is,  
 who both produces corn and cattle, and attends to  
 the dairy, the poultry, the woodlands, and the  
 orchard. A farmer may confine himself to grazing  
 or to breeding or haymaking, or milking or raising  
 green crops for the market, &c. but in none of  
 these cases may he with propriety be called a hus-  
 bandman. This term husbandman, therefore, is  
 not exactly synonymous with farmer.  
**Hosshunt**, the culture of arable grass and wood-  
 lands, the management of live stock, the dairy  
 poultry &c., and, in general, what constitutes the  
 business of the head of a family living by agri-  
 cultural industry in the country.  
**Hosshunt**, backward or apertures, p. 1015.  
**Hosshunt**, the *Thyris glaberrima*, an insect occurring  
 in the skull of the sheep, p. 1005.  
**Hosshunt's rat**, explained, a 7301 p. 1008.  
**Hosshunt**, an instrument for ascertaining the dis-  
 green of moisture in the atmosphere, p. 775.

## I.

**Isle**, the perfect state of insects, p. 1112.  
**Isle**, to strike against, a 4361 p. 719.  
**Is and is system** of breeding, p. 501.  
**Islands** of objects on roads, the marks, traces,  
 tracks, or rule marks, a 5071 p. 578.  
**Islands**, proportional rates of increase, a 5532  
 p. 972.  
**Islands**, peculiar to, springing out of the nature  
 of, p. 1005.  
**Islands**, hatching, p. 715.  
**Islands**, an obsolete dialect term for enclosed lands  
 near the farmstead, as opposed to such as are at  
 a distance from it, and cultivated, a 552 p. 120.  
**Isle**, *see* 5 villages.

**Isle**, the coloured state in the eyes of animals, a  
 5371 p. 570.  
**Islands**, *see* *perpetuity*, explained, p. 474.  
**Islands**, a triangle which has only two of  
 its sides equal, p. 525.  
**Islands**, *see* *Islands*, the books of which  
 are carried from one place of deposit to another,  
 and thence issued, p. 754.  
**Islands**, a variety of pigeon, p. 1005.  
**Islands**, a tool used by miners for boring holes in  
 hard stones to be run by gunpowder, p. 744.  
**Islands**, a long stiff pole, by which persons in  
 the fun are enabled to jump across ditches or  
 drains twenty feet wide, by planting the pole  
 towards the middle of the ditches, and springing  
 from bank to bank, a small piece of board, called  
 a quint, is fastened to the bottom of the pole to  
 prevent its sinking into the mud. *See* *Quint*.

## K.

**Kale**, the name of any description of *Plant* or other  
 seaweed, p. 1205.  
**Kale** for ship-building, crooked pieces of timber,  
 having two branches or arms, and generally used  
 to connect the beams of a ship with her sides,  
 a 5034 p. 491.  
**Kale**, explained, a 6367 p. 972.  
**Kale**, the name given to the cattle of the Ha-  
 lides, a 6705 p. 1015.

## L.

**Lachrymal gland**, the gland which secretes or sup-  
 plies the *lachrymæ* or tears, p. 970.  
**Lactate**, the absorbents of the mammary which  
 originate in the small intestines, and convey  
 the chyle from thence to the thoracic duct, p.  
 505, *see* *Crab's Tech. Diet*.  
**Lactometer**, explained, a 7008 p. 1037.  
**Lampro**, a swelling of the wrinkles or ribs in the  
 roof of the horse's mouth analogous to the gun-  
 nels in man, p. 980.  
**Land**, a term employed in Cambridgehire and  
 other counties, to designate what more generally  
 is termed a ridge; that is, one of these compart-  
 ments which lie between gutter and gutter in  
 arable fields. The ridge, in Cambridgehire, is  
 the highest part or central line of the lands, just  
 as the ridge of a house is the highest part of its  
 roof. In Scotland, a ridge includes the whole of  
 the surface between gutter and gutter. *Land* ap-  
 pears the fitter term.  
**Land**, ground, earthy surface in opposition to wa-  
 ter or rocks. The term ground is generally ap-  
 plied to a comparatively limited extent of surface,  
 as garden grounds, bog grounds, &c. in opposition  
 to arable lands, wood lands, &c.  
**Land fast stones**, stones fixed or imbedded in the  
 soil, p. 453.  
**Land-race**, explained, a 4538 p. 780.  
**Larva**, the grub, maggot, or caterpillar of insects,  
 603.  
**Laryngeal concussus**, the voice of animals, a 6705  
 p. 1015.  
**Larynx**, the windpipe or trachea, p. 972.  
**Lateral shoot**, shoots emitted on the sides of  
 branches; laterally; quite distinct from lateral  
 shoots, with which they are occasionally con-  
 founded, p. 478.  
**Laying** in hedge-planting, laying down the sets  
 or plants horizontally on the bed prepared for  
 them, a 5044 p. 644.  
**Laying an old hedge**, explained, a 5005 p. 490.  
**Laying in**, explained, a 7253 p. 1065.  
**Laying**, property held on lease, p. 608.  
**Legget**, explained, a 5194 p. 514.  
**Leguminous crops**, crops of the various kinds of  
 peas, as peas, beans, vicia, sainfoin, lucern,  
 clover &c., p. 500.  
**Legumens**, explained, p. 505.  
**Leverage**, the act of using levers, or the power ac-  
 quired by the use of them, p. 574.  
**Light-dressed**, the deep-lap of a light colour, a 6705  
 p. 1015.  
**Lignous plants**, woody plants, as trees or shrubs,  
 p. 470.  
**Lipped and holed**, a wall built of stones without  
 mortar but which has the joints afterwards filled  
 with mortar and the whole wall plastered over  
 with what is called rough-cast, or having in Scot-  
 land. The mixture used for herring in lime, sand,  
 and small stones about the size of peas. *Dothing*  
 in England is the feasible coating of small stones

Use the above, only washed quite clean, into the soft recent plaster of exterior walls, in order to resist the action of rain.

**Lime**, any soil in which clay and argillaceous matter exist in considerable proportions, and so as to render it neither very adhesive or hard, nor soft and loose.

**Loaf spit**, explained, a. 682 p. 682.

**Lunge**, a long leather thong, used in the process of lunging or lunging horses, p. 1001.

**Lumps**, a clump, collection, rather viscid humor separated from the blood, and specifically heavier than water, a. 632 p. 637.

**Lymphatics**, lymphatic vessels, are the absorbent vessels that convey the lymph into the thoracic duct, and focus, with the lacteals, what is called the absorbent system. The use of these vessels is to draw in by a capillary attraction the fluids contained in the circumjacent cavities, p. 503. See *Crab's Trak. Dict.*

**Lymphatic abscesses**, 503. See *Lymphatics*, and *Lacteals*.

## M

**Maceration**, the act of steeping or soaking in water p. 863.

**Male acid**, an acid obtained from apples, by saturating the juice with alkali, and pouring in the aqueous solution of lead, until it becomes no more precipitate. See *Crab's Trak. Dict.*

**Mallinders**, a disease in horses, a. 6710 p. 1007.

**Manege riding**, explained, a. 6672 p. 1005.

**Martingale**, a thong of leather fastened at one end to the girth under the belly and at the other to the noseband of the bridle, to prevent a horse from rearing, p. 1001.

**Maturation**, the process of ripening, p. 816.

**Mastatory glands**, the glands belonging to the jaw bones, p. 673.

**Meal** of mill, the quantity yielded at one time of milking, thus, the morning meal, the evening meal, a. 7103 p. 1046.

**Mesline**, marrow p. 967 In plants it signifies the pith.

**Mess or messes**, cattle ponds in Derbyshire, p. 755.

**Messel timber**, fir timber from the part of Messel in Prussia, in the Silesia, p. 804.

**Mere** a lake, pool, or pond.

**Mesentery** a membrane in the cavity of the abdomen attached to the venter of the loins, and to which the intestines adhere, p. 375.

**Meslin**, a union of stocks, a. 735 p. 115.

**Meslin**, meaning mesurin, meslin, or mesclage corn that is mixed, as wheat, rye, &c., to make bread. This term occurs in old acts of parliament for the regulation of rivers, as that of the Ozen; meslin being in former days a frequent landing in that neighbourhood.

**Mesa**, explained, a. 735 p. 118.

**Metacarpus**, the shank, p. 965.

**Metal bed of a road**, explained, a. 3530 p. 586.

**Metastrophic ores**, ores which contain metals, p. 622.

**Metals of a road**, the material of which a road is formed, as broken quarry stone, boulder stones, and other kinds, p. 612.

**Mettage quaters**, the system of farming lands in many parts of the Continent, in which the produce is equally divided between landlord and tenant, p. 184.

**Midden**, dunghill, p. 307 "The midden is the mother of the meal hat."

**Milky** a provincial term for a slave, in which milk is strained, a. 7066 p. 1046.

**Moirure**, holes, cells, or receptacles made in peats, &c. to receive the trunks of reeds, &c., p. 493.

**Mould** organic matter in a finely divided and decomposed state, with a little earth mixed, as vegetable mould, leaf mould, peat mould, &c.

**Mowart**, explained, a. 7137 p. 1023.

**Mow**, a compartment in a barn, into which corn in the straw is stacked or piled.

**Mow-horn** to beat by fermentation in the mow p. 589.

**Murres**, a wasting, contemning, and most fatal disease among cattle, a. 6843 7230.

## N

**Naked disease**, explained, a. 7561 p. 1002.

**Naturalizing embryos and seedlings**, introducing them to a new climate, in such a manner that they shall in future perpetuate themselves in that climate without the aid of man. See *Acclimatizing*

*Naturalizing* or hat bone of the horse, explained, a. 6617 p. 970.

**Niching** See *Docking*.

**Nickering** considered, explained, a. 6579 p. 970.

**Nine**, a variety of pigeon, p. 1065.

**Nurses** for young plants, plants of an trifoliar and rapidly growing kind, planted round those which are choicer and of slower growth, both to shelter them and expedite their growth, p. 525.

## O

**Obliteration**, considerations appertaining to the feelings

calving, yearning, &c. of animals, a. 6803 p. 1005.

**Odometer** from *odos*, a way and *metron*, to measure, an instrument by which the quantity of space passed over on foot, or in a conveyance, may be ascertained, a. 2206 p. 376.

**Oerophagus**, the wrenson or gullot, p. 372.

**Ondatum**, the owl, p. 973.

**One bent stick**, a flagstick formed by the going and returning of the plough, a. 6240 p. 829.

**Ophthalmia**, an inflammation in the coats of the eye, proceeding from arterial blood got out of the vessels, and gathered together between the coats, a. 6768 p. 1012.

**Optic nerve** a nerve which perforates the bulb of the eye, and communicates with the brain; so that every sensation derived from sight depends on the optic nerve, p. 970.

**Outfall**, the lower end of a water-course, p. 714.

**Outfield**, uninclosed farm lands at a distance from the farmstead, a. 803 p. 120.

**Oute**, a variety of pigeon, 1065.

## P

**Pacing**, one of the motions taught the horse, a. 6672 p. 1004.

**Pancroas**, the sweet bread. It is composed of innumerable small glands, the excretory ducts of which unite and form one duct, called the pancreatic duct, that conveys a fluid very similar to saliva into the intestines, called the pancreatic juice, which unites with the chyle in the duodenum.—*Crab.*

**Pans of ground**, a four-sided compartment of grass ground adapted for irrigation, p. 730.

**Panicle**, an irregularly divided branch of flowers, as in the oat, p. 838.

**Panicle** a gutter tile, p. 708.

**Paper mould** washed paper which, when mixed up with glutinous substances, may be moulded into various shapes, p. 810.

**Paring and harrow** taking off the turf or surface of grass or waste lands, and manuring it by means of fire in order to prepare the soil for aration p. 551.

**Parotid glands**, explained, a. 6385 p. 972.

**Passing** one of the motions taught the horse, a. 6672 p. 1005.

**Pasture**, explained, a. 6319 p. 965.

**Pasture**, explained, a. 6385 p. 962.

**Pavilly**, *verruca*, p. 794.

**Peders**, the same as burkers. Persons employed to deprive trees of their peel or bark, p. 602.

**Pellicle** little skin or coat, p. 922.

**Pell rot**, explained, a. 7264 p. 1023.

**Pensile**, explained, a. 7267 p. 1023.

**Pericardiac** the last but one, p. 801.

**Pericardiac** to strain, or tuckle through p. 851.

**Percolation**, the act of straining, purification or separation by straining, p. 522.

**Perforans** of the horse's foot, explained, a. 6490 p. 978.

**Pericardium**, explained, a. 6336 p. 967.

**Pericardium**, explained, a. 6336 p. 967.

**Pericardium**, a general uniting membrane to bones and their appendages, a. 6336 p. 967.

**Pericardium**, the circumference or orbit, p. 428.

**Pericardium**, explained, a. 7251 p. 1023.

**Peristaltic motion**, the vermiform worm-like, or creeping motion of the intestines by which they contract their spiral fibres so as to propel their contents, p. 816.

**Petite** a variety of pigeon, p. 1065.

**Pharynx**, explained, p. 974.

**Picking and knocking** loosening with a pick-axe or mattock, and by separating with some cutting tool, a. 5322 p. 539.

**Picking of hay plantations**, explained, a. 6096 p. 526.

**Pincwork** work done and paid for by the measure of quantity or by previous estimation and agreement,

[illegible]

## GENERAL INDEX.

\* The Numbers refer to the Paragraphs, not to the Pages, except in the case of the List of Authors, where they refer to the page and the year in which the Author published; in such cases the word page and before A.D. are prefixed.

- ABATE**, Antonio, his work on agriculture, page 1261. A. D. 1808.
- ABBE**, F. his work on agriculture, page 1217. A. D. 1791.
- ABERDEENSHIRE**, statistics of, 7882.
- ABORTION** in plants, 1683.
- ABYSSINIA**, climate, surface, and soil of, 1067. agricultural products of, 1066. live stock of 1069. agriculture of, 1070.
- ACCOMMODATION** of plants, 1764. the more tender animals, 7361.
- ACCOUNTS** books, farmers', 6885.
- ACCOUNTS**, keeping and auditing 6708. keeping, 6885. necessity of a regular system of 6301.
- ACID**, fluoric, in animals, 1694. muratic, in animals, 1696. pyrofluoric, distillery of, at Milburn in Dorsetshire, 7843.
- ACIDS**, 1423. oxalic, 1424. acetic, 1425. citric, 1426. malic, 1427. gallic, 1429. tartaric, 1429. benzoic, 1430. prussic, 1431. vegetable, constituents of, 1430. animal, 1433.
- ADAMS**, James, his work on agriculture, page 1810. A. D. 1788.
- ADAMS**, of Blair Adam, 7847.
- ADAMS**, George, his work on agriculture, page 1212. A. D. 1812.
- ADAMS**, Madame Aglaé, her work on agriculture, page 1318. A. D. 1822.
- ADANBOHIA** digitata, 1109.
- AFRICA**, general description of, 1058.
- AFTER** grass on meadows 6815.
- AGRICULTURAL** Institution of Mangelin, 576.
- AGRICULTURAL** Society Australian 1043.
- AGRICULTURAL** Societies of Hanover and Cella 893.
- AGRICULTURE** among the Romans, decline of, 176.
- AGRICULTURE**, as influenced by climate, 1546. by temperature and light, 1550. by elevation, 1550. by soil, 1553. by moisture 1556. by the state of society 1570. by civilization, 1571. by political circumstances, 1572. by religion, 1573. by the character of a people, 1574.
- AGRICULTURE**, bibliography of, 7892.
- AGRICULTURE** during the seventeenth century 534.
- AGRICULTURE** earliest Spanish works on, 713.
- AGRICULTURE**, history of, in the ages of antiquity 5. in Egypt, 8. among the Jews, 17. of the Greeks, 36. of the Romans and Carthaginians, 36. among the Romans, 42. during the middle ages in Italy 136. in France, 136. in Germany 138. in Britain, 136. in ultra-European countries, 47.
- AGRICULTURE**, improvement of, by refining the taste of the purchasers of its products, and increasing the knowledge of agricultural patrons, 7935. by the better education of those engaged in it, 7930.
- AGRICULTURE** in England during the thirteenth and fourteenth centuries, 530. in the fifteenth century 511. in the sixteenth century 515. early in the sixteenth century 520. during the reign of Elizabeth, 525.
- AGRICULTURE** in ultra-European countries during the middle ages, 527, 528.
- AGRICULTURE** may be practised without any knowledge of its theory 1588. object of the art of, 1587. state of the science of, 1585.
- AGRICULTURE** of Britain, classification of the, 1580. improved by the Norman conquest, 504.
- AGRICULTURE** of irrigation, geographical extension of the, 1596. of manures and irrigation, 1595. of draining and manures, 1593. of sowing, 1571. of hedges, 1577. barbedness, 1576. of sowing, 1579. of water and lands, 1595. of sun-burnt lands, 1587. of meadows, 1598. common 1592.
- AGRICULTURE**, origin of and importance. practice of, in early times recent discoveries in arrangement of the subject in this work, pages 1 to 3. the operations, 3111. the physical circumstances affecting 1598. traditional history of, 1, 2, works on, during the commonwealth, 525.
- AGRICULTURIST**, commercial, the different kinds of, 7794. student, 7795. professional education of, 7945.
- AGRICULTURE**, his work on agriculture, page 1213. A. D. 1805.
- AGRICULTURE**, John, his works on agriculture, page 1212. A. D. 1804.
- AIR** fresh, proper for domestic animals, 3075. noxious in walls, 4480.
- AIRTON**, William, his works on agriculture, page 1212. A. D. 1812.
- AIRTON**, his work on agriculture, page 1221. A. D. 1788.
- AIRTON**, Langt, his work on agriculture, page 1221. A. D. 1548.
- ALBANY**, agriculture of, 785.
- ALBANY**, Jacques Antoine, his work on agriculture, page 1222. A. D. 1811.
- ALBRECHT**, J. F. R., his work on agriculture, page 1212. A. D. 1775.
- ALBUMEN**, 1344. 1406. in animals, 1039. use of, 1540.
- ALDEN**, John, M. D., his work on agriculture, page 1211. A. D. 1802.
- ALFALFA**, utility of the, 1553.
- ALGERIA**, description of the territory of, 1055.
- ALKALI**, vegetable, 1500. utility of, 1501.
- ALLIOT**, F. J. Augustus, his works on agriculture, page 1215. A. D. 1780.
- ALMOND** tree, tree, at the Cape of Good Hope, 1132.
- ALOE**, the, in Spain, 723. of the Cape of Good Hope 1123.
- AMASSONIA**, agriculture of, 1544.
- AMBERG**, 1242.
- AMERSON**, Hubert Pascal, his work on agriculture, page 1216. A. D. 1778.
- AMERICA**, agricultural operations of, 1170. field labours in, 1171.
- AMERICA**, North, temperature of the eastern parts of, 9329.
- AMST**, Le F. his work on agriculture, 1216. A. D. 1770.
- AMMONIA** in animals, 1039.
- AMMONIAC**, 1474.
- AMORIN**, his works on agriculture, page 1221. A. D. 1792.
- AMORIN**, his works on agriculture, page 1216. A. D. 1787.
- AMST**, William, his works on agriculture, page 1216. A. D. 1794.
- AMPHIBIA**, 7536.
- ANALYSIS** of plants, mechanical and chemical processes for the, 1594, 1595.
- ANALYSIS** vegetable, products of, 1594. compounds products of, 1595.
- ANDERSON**, James, L. D., his works on agriculture, page 1250. A. D. 1778.
- ANDERSON**, William, his work on agriculture, page 1215. A. D. 1816.
- ANGEL**, the, injuries to young salmon, 3088.
- ANGLO** lessons, origin of the, 503.
- ANGUS**, statistics of, 7650.
- ANIMALS** affected by climate, 1598.
- ANIMALS**, endogenous, 1094. parasitic, 1095. hydrophobic, 1096. dead, as a manure, 1045. distribution of on the face of the globe, 1093. lava distribution of, 1093. domestic, the raising of, 1025.
- ANIMALS**, external covering of, 1044. importance of, in the art, 1013. 1019. as articles of food, 1015. in medicine, 1016. influence of soil and climate

- Beaks of birds, 1822.  
 Beans, *Cercis*, 1324.  
 Bean drill, 2623; *Walter's* expanding, 2626.

 Pitting system of planting, 5845, 5851.  
 Pitting straw 5850.  
 Plan of the, necessity of forming a, 7634.  
 Plans of estates, to make, 5201.  
 Plantain, the, culture of, in the West Indies,  
 1215.  
 Plantations, as shown on farms, 4035; sifting up  
 blanks in, 5825; pruning and heading down  
 trees in, 5827; the formation of, 5823; soil, 5825;  
 5825; preparation of the soil for, 5825; whether  
 should be sown or planted, 5825; disposing the  
 plants in, 5828; mixture of trees in, 5828; insects  
 injurious to, 7631; near roads, 5831; neglected,  
 improvement of, 4265; for shelter, 4265; of service  
 and silver fir, management of, 4078; clearing  
 out, 4009; the proper season for, 4009.  
 Planting, 5145; as applied to seeds and tubers, 5145  
 as applied to plants already originated, 5144.  
 Planting trees, a general principle of guidance in,  
 5010; the best situations for, 5011; near build-  
 ings, 5015 sort of product desired from, 5011;  
 orchard trees, 4105; seasons for 5057 with the  
 diamond dibble 5046; with the planting mallet,  
 5049 with the forest planter or ground edge,  
 5050.  
 Plants, action of the atmosphere on, 5344; of Brazil,  
 with fibres adapted for economic purposes, 1259  
 of Britain, distribution of, 1795; social and anti-  
 social habits of, 1778; colouring 5005; composite  
 organs of, 1573, 1576; elementary organs of,  
 1573, 1576; conservative appendages of, 1573  
 conservative organs of, 1506; constituent ele-  
 ments of, 1510; cotyledons and acotyledons,  
 of Britain, 1797, 1798; distribution of, 1799 1800;  
 geographical distribution of, 1801; cultivated  
 for oil in Hindustan, 500; cultivated for their  
 roots or leaves, 500; nutritive products of,  
 5250; cultivated for their use in the brewery  
 5205 substitutes for 5073; definition of, 1670  
 diseases of, 1805; distribution of with respect to  
 their systematic classifications, 1776 food of,  
 1261; general distribution of, 1723; green succu-  
 lent, as a manure, 5353; herbage, 5518; Sir H.  
 Davy's table of the nutritive products of the  
 principal 5250 imperfect, 1326; to increase the  
 number and improve the nutritive qualities of,  
 1825; injuries and disorders incident to, 1671;  
 introduction of nourishment by, 1826; mag-  
 nesium, 1745; sodium, 1746; champagne, 1750;  
 demise, 1751; rudeness, 1752; sylvatic, 1753;  
 alpine, 1754; parasitical, 1755; domesticated,  
 1756; mode of describing, 1259; the most uni-  
 versal, 1782; the native countries of, 1774; natu-  
 ral sections of, 1758 decay of the temporary or-  
 gans in, 1777; decay of the permanent organs of,  
 1781; physical virtues of, changed by cultivation  
 1680 preparation of, for planting, 5145; description  
 of, in the prepared soil, 5145; reproductive organs  
 of, 1261 appendages of the, 1587; the total num-  
 ber of species of, 1794; the true nourishment of,  
 5147; the two methods of arranging, 1326; useful  
 and edible, of China, 500; virtues of, where red-  
 dent, 1407; of visible sexes, 1777 of invisible  
 sexes, 1778; which distinguish the various kinds  
 of, 5158.  
 Plashing an old hedge, 5035.

 Series of plants, 1462  
 Shade and shelter for certain plants, necessity of 1287

- Shanks, double, advantage of, on roads, 5744.  
Shaken in trees, to remedy 4031.  
Shapes which indicate a propensity to fatten soonest, 3081.  
Sheath, the, or land-guard of loose stones, 4585.  
Sheaves of corn, an improved method of setting up, 3177; methods of drying, 704.  
Sheaving of corn, 5175.  
Sheds, portable, for pasture lands, 6538.  
Sheep, the, 7112; the common, in a wild state, 7113; value of, to the British farmer, 7114.  
Sheep, varieties of 7115; the long-wooled British 7117; the short-wooled, 7118; the hornless breeds 7119; sheep best suited to arable land, 7120; the long-wooled large breeds, 7121; the shorter woolled varieties, 7122; sheep that range over the mountainous districts of Britain, 7123; the Spanish or Marine breed, 7124.  
Sheep, criteria of properties in of an excellent ram 7144; of a sound healthy sheep, 7145; of age 7144; names of the different ages and conditions of sheep, 7145.  
Sheep, breeding, 7146; season of putting the rams to the ewes, 7153; period of gestation, 7154; keep of sheep after lambing, 7159; castrating lambs, 7160; weaning of lambs, 7161.  
Sheep, rearing and management of 7162 on rich grass and arable lands, 7165; treatment of the lambs, 7168; selection of the lamb stock, 7170; selection of the grown stock, 7173; shearing 7173; washing, 7177; marking, 7178; shortening the tails, 7186; rearing and management on hilly and mountainous districts, 7190; store farming 7192.  
Sheep, folding, 7208.  
Sheep, fattening, 7219; fattening lambs, 7234.  
Sheep, the Merino breed, 7240; introduction of 7241; Dr Parr's experiments with 7232; shearing of 723; products of the wool of 7233; Lord Somerville's experiments with 7237.  
Sheep, anatomy and physiology of 7239; skeleton of 7241; the viscera and soft parts, 7242; wool of 7243.  
Sheep, diseases of, 7244; of lambs, 7273.  
Sheep, the Berkshire polled 7790 of Berwickshire, 7635 in Buckinghamshire, 7783; of the Cape of Good Hope, 1187; of the farm of Coldington, near Hansover, 130; of Dorsetshire, management of, 7819; of the Eskdale, 7859 of Hin chelsea, 813; the Hungarian, 634; improvement of, on the farm at Moegelin, 685; in Lancashire shire, 7798; of Perthshire, 7840 of Spain, 735; management of, 737-742; when first fed on the ground with turnips, 687.  
Sheep-shearing in Spain, 741.  
Sheel-fish fishery 5853.  
Shell sand, as a manure, 5283.  
Shell slug, the, 7703.  
Shells of animals 1370.  
Sheepfaring farm-lands, 4584.  
Sheltering and shading lands, 2215, 2216.  
Shepherd, the, 4678.  
Shetland Isles, statistics of the, 7861.  
Sherry, John, his work on agriculture, page 1213. A. D. 1814.  
Shocking of corn, 5175.  
Shoeing of horses in Flanders, 289.  
Shoots, natural, 1502.  
Shorelands, improvement of, 4537.  
Shovel, the, 2445.  
Shovelling, 5194.  
Shropshire, statistics of, 7795.  
Siam, the kingdom of, 549; agriculture of the, 850; soil of the, 351.  
Sicks, for reaping grain crops 5179.  
Sickler F Ch L, his work on agriculture, page 1201. A. D. 1805.  
Sida althifolia, use of, in China, 562.  
Siebe's rotary pump, 4601.  
Sierra Leone, description of, 1105.  
Sieve works on agriculture, p. 1215. A. D. 1798.  
Sieves, 2353.  
Sifting earth or gravel, 5125.  
Sihola in animals, 1936 in plants, 1504.  
Silk culture of in Hungary, 653.  
Silkworms, the, 7225; breeding of, 7236; in the south of France, 411.  
Simonds, J. C. L. his work on agriculture, page 1201. A. D. 1801.  
Sims, Pinder, his works on agriculture, page 1213. A. D. 1814, 1815.

Smiley Andri Louis Marie, his work on agriculture, page 1215. A. D. 1803.  
Society for a landed proprietor's manure, the most desirable, 5528.  
Sofbo farmery 4163.  
Skin and leather, refuse of the manufacture of, as a manure, 5251.  
Skin secretions of the, 1574.  
Skins of animals, use of the, 3077.  
Skirting lands, 3610.  
Sloven plantations, 4585.  
Sleep, the positions assumed by animals during, 1910.  
Sleeping-rooms for night men, 3068.  
Slips, statistics of 7864.  
SMT method of planting, 3047.  
SMT-planting, an expeditious mode of, 3053.  
Slugs, 7705.  
Sluice, a, 4405.  
Smell James, his work on agriculture, page 1200. A. D. 1784.  
Smith, John, his work on agriculture, page 1207. A. D. 1870.  
Smith Rev John, D.D. his work on agriculture, page 1211. A. D. 1798.  
Smith, William, his works on agriculture, page 1212. A. D. 1803.  
Smith's attempt at a reaping machine, 5738; his opinion on irrigation, 4387.  
Smithy on a large farm, 3053.  
Smoking tobacco, antiquity of, 6194.  
Smut, the, in corn, 1853; 2024.  
Smut machine, the, 5706.  
Snail the edible, 7618.  
Snails, 7707.  
Snow, 5576 of great use to the vegetable kingdom, 3577; heat produced from 3594.  
Society, agricultural, 7611; lately formed in Mel-tain, 800.  
Society of Arts, the, 7613.  
Society of Improvers in the Knowledge of Agriculture, in Scotland Institution of the, 763.  
Society state of, as influencing agriculture, 1270.  
Soda in animals, 1932.  
Soderstr, Giovanni Stefano, his work on agriculture, page 1201. A. D. 1625.  
Soil among trees, culture of 3080.  
Soil, as influencing agriculture, 1363.  
Soils, exhaustion of 1534; fertility of, restored 1535; how distinguished from masses of earth 2114; classification of 2117; naming the genera of 2118; naming the species of 2119; table of 2120 to discover the value of, 2121 indicated by the plants growing on them, 2122 the qualities of, discovered by chemical analysis, 2123 the qualities of, discovered mechanically and especially 2127 the absorbent powers of, 2145; peculiar distinctions of 2127; chemical agency of, 2160; improvement of, 2168 pulverisation of, 2163 constitution of, 2173; aeration or blowing of, 2174 alteration of the constituent parts of, 2180 the capacity of, for retaining water to ascertain, 2144; insolubility of, 2191; burning of, 2192; water with respect to, 2193.  
Soils, mixed or secondary 1745; aquatic, for plants, 1744; earthy of plants, 1747; vegetable, of plants, 1723.  
Soils, the most proper for irrigation, 4386; Smith's opinion respecting, 4387; peaty, 3112; spurious peaty 2113; power of vegetables to exhaust, 2519; in respect to farming lands, 4748; retentive, mode of draining, 4867; use of the, to vegetables, 2145, 2148; the constituent parts of, which give tenacity 2140; power of, to absorb water by capillary attraction, 2103; power of, to absorb water from air 2123.  
Solar rays, influence of, on vegetation, 5281.  
Solids, animal, 1207; the soft, 1201; the hard, 1202.  
Solomon Isles, the, 1052.  
Somersetshire, statistics of, 7890.  
Somerville, Right Hon. John, Lord, his works on agriculture page 1211. A. D. 1798.  
Somerville Robert, his work on agriculture, page 1212. A. D. 1805.  
Soot, as a manure, 5265.  
Sopar's waste, as a manure, 2210.  
South America, climate, surface, and soil of, 1262.  
Sowing, 3145.  
Sowing of rice seed in Flanders, 288.  
Spade of the husband, 1159; the Finnish, 2645; used in irrigation, 4305; the trenching, 512.

- Spandau, Philip*, his works on agriculture, page 1222.  
A. D. 1522.
- Spain*, agriculture of, in the middle of the 18th century, 714 during the 19th century, 115 climate of, 715; surface of, 717, soil of, 718, landed property of, 719, land features in the old government of, 720 agricultural products of, 731 rotations of common crops in, 735 live stock of the agriculturist in, 734, sheep of 735 implements of agriculture in, 744, operations of agriculture in 745, forests in, 747 improvement of agriculture in, 748, cause of the decline of agriculture in, 718.

## INTRODUCTION.

---

THE improvements in agricultural science and practice, which have been either discovered, or brought more conspicuously into notice, since the publication of the last edition of this *Encyclopædia* in 1851 may be thus briefly enumerated.

1. The functions of the leaves of plants are beginning to be more generally understood; and hence, also, the importance of allowing sufficient space for their exposure to the sun and air by wider sowing or planting, by judicious thinning, and by pruning.

Hence, also, when plants are to be destroyed, this may be effectually done by cutting off their incipient leaves as fast as they appear. In this way ferns and other perennial weeds in pastures may be more easily destroyed than by any other mode and the same may be said of weeds growing up from the bottoms of ponds.

As a proof that the use of leaves was not understood by practical men, and even by the officers of the Highland and Agricultural Society of Scotland, so lately as 1836, we may refer to the *Transactions* of that body in which we find the Society giving a premium for an essay on the destruction of ferns in pastures, to a candidate who recommends as the best mode the irrigation of these pastures. The irrigation of pastures on which ferns abound may be considered unpracticable in ninety-nine cases out of a hundred.

2. Growth and maturation in plants are two separate processes, and when either is the main object of culture, the other should be prevented or checked thus when seeds or fruits are maturing the elongation of shoots and the production of leaves should be checked, by pinching them off as fast as they appear. Hence the use of topping beans, tobacco, wood, and even potatoes not to mention vines, gooseberries, raspberries, peaches, and other garden fruit shrubs and trees.

3. By preventing the formation of seeds or fruits, more strength is thrown into the plant generally and if it is a plant which produces bulbs, tubers, or underground stems, as substitutes for seeds, these will be increased in size. Hence the use of picking off the blossoms of potatoes.

4. Plants imbibe nourishment from the soil, chiefly from the points of the fibres at the extremities of their roots. Hence the practice of banking up hedges, beans, potatoes, and other plants in drills, and of watering stirring the soil, and laying manure close to the stems of trees and plants, is erroneous in principle and often injurious in effect; by cutting off the fibrils, or in the case of potatoes, the underground shoots on which the potatoes are formed. In some cases, however cutting off the extremities of the roots is useful by increasing the number of fibrils, and consequently of the spongiolæ or mouths by which nourishment is imbibed.

Hence the Berwickshire practice of tabling hedges so much recommended, and so generally followed by Scotch bailiffs, foresters, and hedgers, is for the most part a waste of labour unless, indeed, the object be to stunt the growth of the hedge, and prevent its roots from robbing the soil of the adjoining fields. The practice of earthing up turnips was once in vogue, but it is now ascertained to be a certain mode of instantly checking the swelling of the turnip, by the pressure of the soil which is thrown up to it by the plough.

5. The properties of the fruit of any plant, for example, the gluten of Leguminosæ or wheat, or the starch of potatoes, or the sugar of the beet-root, are more or less diffused over the entire plant and hence sugar may be made out of the leaves of the beet, as well as the roots, and starch out of the stems of the potato, as well as out of its tubers; it being understood that the leaves or stems are in a nearly mature state.

6. The progress of the ripening of seeds and fruits in general goes on in a geometrical ratio, and hence the great moiety required to determine the moment when seeds or fruits should be gathered, which period varies according to the purpose to which the seeds or fruits are to be applied. The last change which takes place in the ripening of wheat is an increase of bran or husk, and a relative diminution of starchy matter or flour and hence the immense difference in the produce in flour, between that of the grain of a field of wheat cut down at the proper time, and a field of wheat allowed to be over ripe. Too much importance can hardly be attached to this subject.

7. Running water is found to contain oxygen, potash, carbonic acid gas, and ammonia, all which serving as manures for plants, it follows that irrigation, even in cold climates, is beneficial to grass lands, altogether independently of supplying water as an element of growth, which in cold climates is seldom wanted in that capacity.

8. More importance is now being attached to the ascertaining of the mineral constituents of plants, such as alkalies and alkaline earths, phosphorus, sulphuric acid, silica, &c., than was the case before the appearance of Liebig's *Organic Chemistry*.

9. The permanent fertility of a soil is found to depend more on the inorganic substances which it contains, (for example, on the proportion of alkalies and alkaline earths which it holds in combination with the silica, phosphoric, sulphuric, and other acids,) than on its organic constituents, such as humus or decaying vegetable matter: for all organic matter in soil, whether that soil be naturally good or bad, is sooner or later exhausted by the growth of plants and if the supply is not kept up, the soil reverts to its original state, except in so far as it may have been improved mechanically by draining, levelling, shelter, &c.

10. Plants absorb their carbon chiefly in the form of carbonic acid, and not, as was supposed till lately solely in the form of a solution of humus.

11. Plants derive their carbonic acid principally from the atmosphere in the form of carbonic acid gas; and the chief use of humus or mould in the soil, is to combine with the oxygen of the atmosphere, and thus to supply an atmosphere of carbonic acid to the roots. Hence the infertility and often dead loss, of burying putrescent manure to such a depth as to exclude it from the air and the more immediate return made by manure spread on the surface of the ground among the leaves of plants, as in manuring meadow lands, and top-dressing spring crops of corn, or artificial grasses.

12. The process by which carbonic acid is generated by oxygen from humus, depends on the soil being permeable to air and moisture and hence one of the principal uses of draining and pulverisation.

13. Alkalies are the most important inorganic constituents of soils, and when a soil has been exhausted of them by cropping, no manure that does not contain alkalies will restore their fertility for agricultural plants.

14. The poorest soils are almost invariably those which contain least alkalies and alkaline earths.

15. Animal manures contain a much greater proportion of the inorganic constituents of plants, than vegetable manures and the most powerful of animal manures are those of carnivorous or omnivorous animals for example, of the human species.

16. The most valuable part of manure is ammonia, from which plants derive their nitrogen, which, though formed only in small quantities in plants, is yet essential to the ripening of their seeds; and hence the great value of urine.

17. Next to ammonia, the most valuable manure is potash, which in the form of silicate is the principal constituent in the straw of wheat.

18. In consequence of knowing the ingredients which constitute a good soil, all lands the slope of the surface of which is not so great as mechanically to prevent their being readily cultivated, may by the addition of the ingredients wanting, and by proper culture, be raised to the highest point of production that the climate in which they are situated will admit of.

19. To know what can be effected in the worst soils in any given climate, it is necessary to have a conception of what can be done on the best soils in such a climate. Twelve bolls (48 Winchester bushels) per statute acre is not an uncommon crop in the best soils and situations in the Lothians and less than 10 bolls (40 bushels) per acre is not considered a full crop. The average produce of wheat in England and Wales, however is only 2½ bolls, or 26 bushels, per acre! It is believed by most scientific agriculturists that every soil and situation in Britain, capable of growing wheat at all, is capable of growing from 8 to 10 bolls or sheaves (32 to 40 bushels) per acre, if properly cultivated.

20. Next to animal manures, the most important ingredient that can be added to soils is the ash of plants, because it contains all their saline constituents.

21. Saline manures not only supply food, but, acting as stimulants, enable plants to derive more food from the soil and the atmosphere than they otherwise would do. (*Chatterly in Phil. Mag.* 1843.)

22. Plants containing the smallest quantity of alkaline salts flourish in the greatest variety of soils, and the contrary.

23. The office of food is two-fold: to supply the body with nutriment or flesh, and to supply heat and fat.

24. Only those substances can supply flesh which contain nitrogen and starch, sugar, gum, and other substances which contain carbon, oxygen, and hydrogen, without nitrogen, only supply heat and fat.

Hence neither pigs nor human beings who live chiefly on potatoes can derive flesh from that kind of food, without the addition of milk, or some other animal matter or of corn, pulse, or meal of some kind which contains gluten. Hence the Irishman's cow is as essential to his existence as his potato ground.

25. Hence a knowledge of the chemical constituents of plants is useful, not only in

ascertaining the manures proper for being applied to them, but also for knowing their application to the feeding or fattening of animals.

Hence, also, no system of agriculture or horticulture can be considered complete which does not give an analysis of the chemical constituents, not only of the plants of cultivation, but of the weeds of the locality. In a word, the chemical constituents of every individual plant are just as essential to be known as its physiology and systematic character; and indeed a great deal more so. A century hence, or in less time, it will be wondered by scientific cultivators how the present generation could go on without this knowledge.

26. Warmth, to a certain extent, is equivalent to food and hence the great benefit derived from sheltering cattle during winter.

27. Exercise is for the most part a waste of food, and hence the advantage of stall feeding cattle, and confining pigs and poultry in a limited space. It does not follow from this, however, that confinement should be carried so far as to render the flesh of the animals unwholesome.

28. In the case of milk cows, rich pastures, or other food abounding in carbon, produce the greatest proportion of butter while poor pastures, by requiring the cow to take more exercise, increase the proportion of the caseous part of the milk.

29. The various new manures which have been introduced are either of organic or inorganic origin. The action of inorganic manures, such as nitrate of soda, common salt, &c. is not uniform, and in some cases is not perceptible but the action of organic manures, such as guano, poudrette, rape or oil cake, and vegetable alkalies, such as potash, is certain, and always beneficial if not applied in too great doses.

30. All clays contain potash, and also all soils produced from rocks containing felspar scoria, albite, and mica and hence one cause of the value of basaltic and granitic soils.

31. The application of burnt lime to clay independently of other effects which it may produce, liberates potash.

32. The action of burnt clay (which generally contains oxide of iron) to soils, independently of its mechanical properties, is as an absorbent of ammonia from the atmosphere.

33. The addition of clay to sandy soils containing calcareous matter increases the quantity of potash which they contain but if the sand contains no calcareous matter it merely improves their mechanical texture.

34. The ammonia of liquid or other manures may be fixed by gypsum or sulphuric acid or in default of these it may be prevented from evaporating by mixing with soil or diluting with water. In general the most convenient and economic mode for the British agriculturist is to mix it with farm-yard manure, or, what is better in our opinion, plenty of surface soil.

35. The chief practical advantages which have as yet resulted from the recent discoveries in chemistry as applied to agriculture, are, the employment of saline manures, and the recognition of their importance, the mixing of atomised (nitrogenised) with unatomised (unnitrogenised) food in feeding and fattening cattle, and the procuring greater warmth for the domestic animals of the farm.

36. The most useful practices which have obtained extended diffusion within the last ten years are, the frequent drain system, long practised in Essex and Suffolk, but recently brought conspicuously into notice by Mr Smith of Deenston, the use of draining tiles instead of stones, the use of the subsoil plough, and of the cultivator as a substitute for the plough in various cases, the greater eagerness to procure improved implements, machines, and buildings generally the mixture of soils, the greater value set on urine and liquid manure generally the use of single horse carts, the selection of improved varieties both of animals and plants, and the employment of land agents conversant with agriculture instead of lawyers or others who have little or no agricultural knowledge.

The details which have led to the above summary will be found in Liebig's *Organic Chemistry and Animal Chemistry*, Johnston's *Agricultural Chemistry*, Trimmer's *Practical Chemistry for Farmers and Landowners*, Solley's *Rural Chemistry*, Dr Playfair's *Lectures on rearing and feeding Cattle*, published in the *Journal of the Royal Agricultural Society* vol. iv Donaldson's *Manures, Agricultural Grasses, and General Management of Landed Property*, &c. The greater part of this Supplement consists of extracts from these works and from the *Quarterly Journal of Agriculture*, the *British Farmer's Magazine*, the *Gardener's Chronicle*, and the *Gardener's Magazine*.

TO THE

## ENCYCLOPÆDIA OF AGRICULTURE

### PART I

#### AGRICULTURE CONSIDERED AS TO ITS ORIGIN, PROGRESS, AND PRESENT STATE, ETC. (p 4)

##### ITALY

7961 — 374 *An oil*, not fit for the table but useful for burning and other purposes, has been obtained by expression from the fruit (kays) of the *Negundo fraxinifolia*. The experiment is of some importance with reference to Briolan, as it shows that in all probability an oil may be obtained from the kays of the common spicamore, *Acer Pseudo-Fraxinus* and also from the common maple *Acer campestre*. See the details respecting the oil obtained from the negundo in *Gard Mag* 1843, p 40.

7962 — 368. The *olive* we are informed by Manetti is propagated by cuttings by seedlings, and by grafting. By cuttings is the most valuable mode when the soil is good, as the plants come sooner into a bearing state. Where the soil is poor and especially if it be rocky seedlings are to be preferred, because they send down their tap-roots into the crevices of rocks, and thus derive nourishment and support, whereas plants raised from cuttings would not live. In Tuscany the olive is very generally raised from seed, and in many situations it is grafted. In Lombardy, on the Larian Hills, trees raised from cuttings are always used, and this is the reason Manetti alleges why these trees have their trunks perpendicular to the sides of the hill instead of perpendicular to the horizon. Some interesting discussion on this very singular appearance will be found in *Gard Mag* vol vii p 68 to 70.

7963 — 359. The cause of *malaria*, in this and other pestilential districts of Italy has generally been supposed to be the decomposition of vegetable matter on a moist surface. This however, is to be confuted the malaria with the marsh fever. The former is now thought to proceed from a very different cause and to be analogous to what in England is called the hay fever. It is found that while the corn or hay crop is in a growing state in the pestilential districts, they are as healthy as any part of Italy; but that the moment the crop is cut down, or withers on the ground, the malaria commences, and continues through the autumn and winter till vegetation becomes vigorous in the following spring. The neighbourhood of Rome where malaria is so prevalent, is a very hilly dry and entirely without vegetation. For days together one sees nothing but desolate dried-up cornfields without trees bushes or wood of any description. In early times Rome was surrounded by extensive sacred woods, which were not suffered to be destroyed. At that period malaria was unknown, though intermitting fevers were well known in the Pontine marshes. (Jenkinson's *Journal*, vol xvii p 187.) In several districts in England, the country people are liable to attacks of fever immediately after the removal of the hay crop some individuals much more so than others. This may be considered as a species of malaria of a comparatively mild description. See on the agriculture of Italy generally an extract from the agricultural part of the *Arti della Terra Romane degli Scienziati Italiani*, Florence, 1842, 4to. in the *Gardener's Chronicle* for 1843. No kind of potatoes has hitherto succeeded in Tuscany owing to the great drought and heat, which destroy the herbage in the month of August. In mountainous situations they succeed better but they are for the most part grown only in gardens where they can be constantly watered. The sweet potato, *Convolvulus Eschsch* succeeds much better as it naturally can stand a greater degree of heat, while its copious herbage covers the ground retains moisture and affords a superior fodder for cattle. (G C 1843, p. 579.)

##### FRANCE.

7964 — 356. The backwardness of agriculture in France "is mainly attributable to the very partial spread of education in the rural districts, there being out of 46,000 communes, according to M. Dupin, 15,000 destitute of teachers; and out of 35,000,000 inhabitants who have reached a teachable age, 18,000,000 only are able to read. Now as the small independent proprietors of land amount to 4,000,000, and their families to 15,000,000 or 16,000,000 more, it is obvious that this state of ignorance must, under such circumstances, be attended with far more prejudicial effects upon production than if it existed in England, where the labourers are under the orders of about 22,000 large proprietors, and the success of cultivation consequently does not so mainly depend upon the general diffusion of knowledge. It is gratifying to find however that the large proprietors in France are universally desirous for the instruction of the rest, and that societies, rural schools and Sunday farms have been established under very liberal able auspices." (For *Export*, Nov 1839.) A national system of public instruction was established in 1838, and the various details will be found in the *Revue de la Société pour l'Instruction Publique*, for that year. An account of the present state of French agriculture, and of the state establishments in that country, such as sheep farms model farms veterinary schools, hares or studs, will be found in the *Journal of the Agricultural Society of England*, vol. I for 1839, p 302; and the statistics of French agriculture is given in the same work, vol I p 411.

7965 — 361. *Present state of French agriculture.* In *L'Agricome*, a monthly agricultural journal published in France, at the low price of five francs a year it is stated in the first number published in January, 1838, that in France "the colonies afford no longer the means of making a fortune, the savants do not provide a remedy for the want of foresight of parents; the system of peace, which is every day procuring more advocates among the most highly civilized of the people, no longer offers a brilliant

prosperity in the production of arms; commerce and manufacture still only particular characters. The sciences and the professions only invade privileged by nature; while agriculture alone offers unlimited scope for employment and for improvement." After enlarging on this subject, the writer goes on to state, that the business of a farmer is not so large as that of a man who is not at for any thing else; but it must be adopted by men of education, and pursued assiduously and systematically. It appears, from this and other French publications, that extraordinary exertions are making in France for the territorial improvement of that country. Among other points to which the attention of the cultivator is directed, is the necessity of feeding his men well, no less than his horses. As a proof of the advantages of doing so, it is stated that when Messrs. Mangles and Wilson, from England, established their iron works at Charenton, the French workmen were not able to support labour for the same number of hours as the English did, till they adopted, like them, the practice of eating butcher's meat. Exactly the same thing has been proved respecting the Irish labourers, as compared with the English, and British soldiers, as compared with those of other nations.

1793. *Agricultural Societies in France.* This, and some of the following paragraphs are taken from a very interesting article, understood to be by Professor Macculloch, which appeared in the *Foreign Quarterly Review*, just after the historical part of our 3d edition of this Encyclopædia was printed. "The Agricultural Society of the Seine and Oise, which comprises many extensive landed proprietors, bestows, annually medals and prizes on the small cultivators who turn their hereditary estates to the most profit, and upon the hired labourers and servants employed in large farms who perform their work with the greatest intelligence and fidelity. A model farm has been lately established at Noville, in the Valley of the Marne about six leagues from Nancy, by M. de Dombasle, a skilful practical agriculturist. It comprises clay sand, and gravelly soil, and the proper modes of culture are applied to each. By the improvements in ploughs and instruments of husbandry five horses and nine oxen now accomplish at Noville more work than thirty-five beasts of burthen used to do on the same ground. With the aid of the Scotch threshing machine, M. de Dombasle beats out with three horses, three hectolitres and a half (equivalent of an imperial quarter) of wheat and other grain in proportion. Potatoes are cultivated with attention, and a distillery has been established for extracting their spirit. M. de Dombasle has proved what will, we think, excite some surprise, that land of a middling quality planted with potatoes for fattening beasts, will be more productive than the richest meadow. No stronger encodement can be made on the skill of M. de Dombasle than the fact that he has more than doubled the produce of the land—the average annual return of Noville being 50 francs per hectare (of 2½ acres), while that of the rest of the department of the Marne is but 25½ francs per hectare. At Montcy, in the department of the Moselle, the model-farm of M. Bouchotte is famous for its breed of horses." (*For Query Rev.*)

1797. *The Agricultural Society of Strasbourg* in 1838 commenced an experimental plantation of fruit and forest trees in Alsace; a want observable not merely in that department, but throughout the whole country except perhaps, Normandy and parts of Brittany. In Franche-Comté, and the department of Doubs, the government has taken the breeding of cattle under its peculiar care, and established annual exhibitions and prizes. In these parts as also in Montbéliard, the useless practice of feeding off the land is beginning to be discontinued. It being ascertained that a hectare of inclosed ground produces one third more if not subjected to this ceremony. The arrondissement of Montbéliard has abandoned the system of fallows in use in the rest of the department; and cultivators with success both flax and the turnip. In Franche-Comté the very heaviest and becoming industrious they go about collecting manure till they have accumulated a certain quantity when they take it to a proprietor who allows them in return to plant on his soil, and receive the crop of a proportionate number of potatoes. In Picardy, the increase of the sheep-locks, and the improved system of manuring, have added to the fertility of the soil. At Novvieux in the department of the Aisne, the farms have been ornamented by hedges and plantations, in imitation of the rich country of Eastman. It is here that the making of sabots, among other useful trades called *bois jolis*, is chiefly carried on; the supply sent to Paris annually is valued at 17,000*l*. At Origny in the neighbourhood of Vervins the children of the husbandmen are employed in tax making, baskets, &c. of willow to the value of 40,000*l* per annum. In Champagne, the example of M. Rickardet, a small proprietor has given an impulse to planting, and to a systematic irrigation of the land." (*Ibid.*)

1798. — 303 & 414. *The culture of the vine* is a department of their husbandry of which the French have, perhaps, a right to boast more than any other people. The same grape, when tried in countries under the same latitude as the south of France has never been brought to an equal degree of perfection. The plantations of vines have been and are subject to severe discouragements but have nevertheless, increased very considerably over their extent in 1788. In that year their surface was estimated at 1,300,000 hectares of land; in 1808, it amounted to 1,600,000; and in 1824 it covered 1,728,000 hectares. In 1828, the vines occupied about 3,600,000 cultivators, and their annual produce was computed at 40,000,000 hectolitres; the value of which, at fifteen francs per hectolitre, is 600,000,000 francs or about 24,000,000 sterling English money (*Ibid.*)

1798. — 301. *The olive* *oléagine* Strabo (lib. iv.) says, that the line of the Cevennes, in Gallia Narbonensis, was the northern limit, beyond which the cold prevented the growth of the olive. The olive is still in the same position. (*Journal de Jour.* April 1824 p. 328.)

1799. — 350 & 350. *The breed of cattle and sheep in France* "with the exception of parts of French Flanders, Normandy and Alsace, is yet very degenerate. But their improvement, like that of mutton, depends upon their rearing; and, if the example of the Noville and other studs be followed, there seems no reason to doubt that the French horses may one day equal those of England or Spain. The company lately formed for recovering the 4,000,000 hectares of March land now uncultivated, and converting them into pasture, will greatly further the amelioration of the cattle as well as the augmentation of their numbers. 3,800,000 horses, 7,000,000 horned cattle and 49,000,000 sheep and goats are certainly not a large stock for a country covering 55,500,000 hectares of land. The most experienced of the agriculturists have shown that the flocks may be brought to almost any desired degree of perfection. When the merino of Spain first appeared in France the portions of the coarse mutton-wool were continually alleging that Spanish sheep could never thrive in the French climate; their success has however been complete. The celebrated M. Ternaux (deceased in 1822) imported wools of what are called the electoral race, and placed the goats of Thibet, in his park of St. Ours, near Paris. The rugged declivities of the Jura have been adorned with the magnificent sax breed of MM. Girod and Perrault, and their rams are now attracting in New Holland the march of science in the management of flocks in France." (*For Query, Rev.*)

1791. — 408. "The French pig, although they have excited many fanciful observations from travellers, and have not unexpressly been compared to greyhounds, may be fattened, we are assured, at a small expense; and the method of doing this is now beginning to be better understood. The Chinese and English breeds are also getting into use for crossing. The fact that 4,000,000 pigs are killed yearly in France, shows of how great importance they are to the small agriculturist." (*Ibid.*)

1792. — 407. *The most extensive of the branches of French agriculture, as compared with the manufactures* "are the culture of beet-root for sugar; of oleaginous plants, particularly at Lille and Dijon, and of the mulberry for silk-worms, in Languedoc and the southern provinces. It has been the habit in England to consider the summer of these as merely a fanciful amusement of national vanity; but it appears by the amount of its consumption (between 7,500,000 and 8,000,000 lbs. a year) that at all events it is become an article of some practical importance." (*Ibid.*) "The process of obtaining sugar from the beet-root has been given in all its details, with a view to adopting the practice in Britain, in the *Brit. Farm. Mag.*, vol. 2. & 21, for 1826 & 1827.

## HOLLAND.

1795. — 425. *The greatest part of the land in Holland, it is observed by Mr. Aiton, of Hamilton, being under the level of the sea, and of the great rivers and canals which intersect that country and, consequently, being unfit for arable culture, is generally kept in meadow.* "Part of the great produce is cut for hay to supply the stock in winter and spring; and the rest of it is eaten off by a few sheep and horses, but chiefly by cows. Some of the cows are fattened for the slaughter, but most of them are kept as dairy stock. In those parts where the surface of the ground is above the level of the water, it is cropped with wheat, rye, rape, beans, oats, flax, hemp, and potatoes, and even where the soil is a little lower than the level of the sea and rivers, part of it is dug up in some places, and cropped with potatoes, hemp, &c. But the greatest part of North and South Holland is so often overflowed with water as to render it improper to raise winter wheat crops to a great extent." (*Genl. Jour. of Agr.* vol. iv. p. 281.)

The soil being generally rich, the herbage is luxuriant; but, owing to the moist condition of the land, which is frequently inundated in winter, the herbage is produced in rather coarse and many moist plants arise from the richer natural grasses. (Ibid.)

1794. *There are five large estates in Holland, and but few large farms.* The land being remarkably level, it is generally divided and subdivided by ditches, or narrow canals that receive the surface water and serve the purposes of a fence." (Ibid.)

1795. — 426. *The farm-houses in Holland* "are of dimensions suited to the extent of the land in the farms, and they are more or less elegant or comfortable, as the wealth or taste of the occupant may dictate; but they very much resemble each other. They are generally of only one story in height, but placed on so broad a base, as to afford accommodation not only for the boer or farmer, and his family, but also their live stock, dairy cheese-house, threshing-floor, the whole crop, and fodder for cattle. In short, the whole farmstead is frequently comprehended under one roof. Besides a kitchen, in which the family sit and eat, as well as cook their food, and from which they can see their cattle during winter and spring, these houses contain at least one elegant and well-furnished room with a bed-room or two, into which they seldom enter except on days of festivity. Their kitchens are much more tastefully fitted up than those of the farm-houses in Scotland. They have a stove of an elegant figure, which is kept wonderfully clean. The wall near the fire-place is covered with plates of shaven earthenware, and the mantelpiece is richly though rather heavily fitted up. There are some concealed beds and closets in this part of the building; while a pump well, and a horse-gin for washing and churning the butter, are both at hand, near the centre of the building. The floor of the kitchen generally consists of marble; the rest of the building is of brick. The gin-course is laid with sand and is covered with boards when the horses are not in use. The whole built with tiles, and the roof rises in a somewhat pyramidal form. The walls are generally built of brick, but sometimes of mud or boards; but the roof is supported on frames of wood round which the walls form only a covering. There is no urine tank as in Belgium. Indeed, little attention seems to be paid to manure in Holland, probably on account of the soil being naturally rich." (Ibid.)

1796. *The cow here is* "paved with hard bricks, or clinkers, as they are termed, set on edge; and the stakes to which the cows are bound are made to be removed in summer when the cattle are turned out to pasture. A passage before the cow's head is convenient for giving them their meat, and a trough of clean water is placed before the cows, from which they can drink at pleasure. The water is let off once a day by means of a plug and a new supply from the well pumped into the trough. A passage behind the cows serves to remove the dung." (Ibid. p. 280.)

1797. *Dutch cows.* The Vriesland and Graveling cows are the largest and most esteemed races in Holland. They are short-necked, broad and deep-chested, deep bodied, and broad-backed with well made limbs fine small horns and stand well upon their feet. The greatest number of these cows are either black or white or dark brown and white. (*Highland Soc. Trans.* vol. x. p. 169.)

1798. *The general practice in Holland is,* "that the cow should calve in her second year. The bull is employed when it is two years old and is fed and sold to the butcher when four or five years old, and the cow at seven or eight. Some cows are, however, kept for milking till the tenth year." (Ibid.)

1799. *The most improved method of treating the calf in Holland* "It is immediately after its birth taken from the cow put in a separate place, and laid on dry straw. A little salt is given and the tongue and mouth are rubbed with it. It is also rubbed clean with straw. After the lapse of six or eight hours, the first teatling of the mother cow diluted with one third water is given to the calf to drink, and this treatment is continued for some days the liquid being given thrice a day. Thereafter during two or three weeks they give the calf the milk as it comes from the cow diluted with one fourth water, in which now and then a small handful of salt is put. Then buttermilk is gradually given and it is supplied with hay; at the age of ten weeks it is brought out into the meadow where it is also supplied with skimmed milk, buttermilk, or whey. In this way each farmer raises the proper number of better calves to fill up vacancies; but calves fattened for sale have no milk from the cow three times a day. For some days after calving the cow is milked thrice a day after which they return to the usual practice of milking twice a day." (Ibid.)

1800. *Treatment of milch cows in Holland.* The cows are turned out to grass generally by the end of March, or the beginning of April. They are, when first sent out furnished with a very thick cloth of tow covering the back and sides from the shoulders to the tail to prevent diseases from cold. They remain out, night and day about thirty weeks. In the winter months the general food is hay and most farmers give their cows nothing else. Distillery grains are sometimes given, when they can be obtained. At the great establishment of Baron Van Falink, near Leyden, hotted beans with rape cake spread over the hay were given at night, and ground linseed cake in the morning which, it was stated, enabled the cow to give more and better milk than hay alone. Bare potatoes and dry linseed cake are also sometimes given, and most farmers give the buttermilk, either diluted with water or not, to the cows, as well as to the calves and pigs. Mangold-wurtzel is also given, but turnips never. (Ibid.)

1801. *The byres or cow-houses in Holland* "are generally lofty airy, paved with large square bricks [Aiton says "clinkers," see p. 7996], and kept perfectly clean. The roof is generally about ten feet high. There are no racks or mangers. The cows stand in two rows, generally facing the centre, and sometimes the sides of the byre, along which is a brick pavement slightly elevated in the middle. On the edges next the cows, and on a level with them is a trough, perfectly clean, into which the mast or drink is put, and the hay laid down. Each cow has about five feet of space, and is tied to a railing of three small posts in front, which separate them from one another. There is a little straw used for bedding on the place where the cows stand, there is a hollow part at the fore feet, into which we now and then put dry horse-dung and straw; at the hind feet, generally nothing is laid but a little dry sand. From the narrowness of the space divided into stalls the back always projects so far as to cause the dung droppings to fall into a gutter about eighteen inches deep and eighteen inches wide, which is regularly and carefully swept and cleaned, so that there is very little trouble in clearing away and collecting the manure. The cows are always kept very clean; and, to prevent the tail concealing filth, the lower end is always tied up by a string attached to the collar." (Ibid.)

1802. *Process of milking in Holland.* "The cows are always milked by the men, and the butter and cheese made by the women. One man is considered necessary for every ten cows. At Ter Lohde, the well-managed dairy establishment of Baron Van Falink, there are ninety milch cows, three men and a Javanese (or female farmer) the maker of the butter and cheese, who has a female assistant. At Eindhoven, near Beersheim, there are forty cows; the farmer and three grown sons do all the milking, and his wife and one female servant make all the butter and cheese. At Schoon, near Haarlem, there are

twenty cows the father and son milk, and the wife and a female servant make the butter and cheese." (*Holland and Fries* vol. x.)

**5002 Butter.** "There are three distinct kinds of butter manufactured in Holland; the butter made from the cream, when the cows are at grass in the summer, called *grass butter*; the butter from the whey of the new milk cheese, called *wey butter*; and the butter made in winter when the cows are in the cow-houses, called *hay butter*." (*Ibid.*)

**5004 Grass butter.** "The cows being carefully milked to the last drop the copper piteghers lined with brass or pitchers acidity of brass, which contain the milk, are put into an oblong water-tight pit which they call a *ruisdel*, built of brick or stone, about six feet in length, three feet in breadth, and two feet in depth, into which cold water had been previously pumped; there being generally a pump at one end of the pit. In this pit or cooler the pitchers stand two hours, the milk being frequently stirred. The cool being present is of great advantage in causing the cream to separate rapidly and abundantly from the milk. After this, the milk, being run through horse-hair sieves or strainers, is put into the last milk-dishes which are of earthenware, copper, or wood as will be afterwards described. It remains in a cool dairy or cellar for twenty-four hours. It is then skimmed, and the cream is collected in a tub or barrel. When secured, if there is a moderate quantity from the number of cows, they churn every twenty-four hours the churn being half filled with the soured cream. A little boiled warm water is added in winter, to give the whole the proper degree of heat and in very warm weather the cream is first cooled in the *ruisdel* or cooler. In many small farm-houses, or when the cows give little milk, the milk is not skimmed, but the whole, when cooled, is put into the churn. The butter immediately after being taken out, is put into a shallow tub called a *ched*, and carefully washed with pure cold water. It is then worked with aallet sprinkling of small salt, whether for immediate use or for the barrel there being none made entirely without salt, as is decided. When the cows have been only eight or ten days out, the difference between grass and hay butter is slightly perceptible but the grass butter after the cows have been three weeks at grass, is delicious. This new butter is highly esteemed in Holland. It is made in fanciful shapes of hams, pyramids, &c. or stuck with the flowers of the polyanthus, &c. and sells very high. If intended for bartering, the butter is worked up twice or thrice a day with soft fine salt, for three days, in a flat tub there being about two pounds of this salt allowed for fourteen pounds of butter. The butter is then hard packed in this layers into the casks which casks are previously carefully seasoned and cleaned. These casks are always of oak, well smoothed inside and, before being used they are allowed to stand three or four days, filled with sour whey and are then carefully washed out and dried. Each cow after having some time at grass, yields about one Dutch lb (17½ oz) of butter per day. (*Ibid.*)

**5005 Hay butter.** "undergoes the same process as grass butter, being of course the butter made in winter, when the cows stand in the cow house. But, although inferior in flavour and colour it has none of the disagreeable taste which the turnip imparts to the winter butter of Britain." (*Ibid.*)

**5006 Wey butter.** "is made from the whey of the new milk cheese. The whey being collected from the curd and the pressed cheese, is allowed to stand three days or a week, according to the quantity; the cream is either skimmed off and churned, or the whey itself is put into the churn and the butter is formed in about an hour. In winter the butter obtained by this process is about one lb per cow per week and in summer about one lb and a half per cow per week." (*Ibid.*)

**5007 Cheese.** There are four kinds of staple cheese made in Holland the round or bullet cheese called *Edam* (from their having been first principally made in that neighbourhood). *Stolkche* (so called from the village of Stolkwyk) which are called in Britain, *Gouda*, and are flat, and broader and larger than the *Edam*, both kinds being made of unskimmed milk. *Ledeche* or *Leyden* (being so called from this kind of cheese being principally made near Leyden) which is made of milk once skimmed, and *Grauwche* which is made in Friesland, of milk twice skimmed. Both the latter kinds are called *Kanter cheese* in Britain, and are larger and flatter than the two first named. (*Ibid.*)

**5008 Edam cheese.** The process of manufacture of the *Edam* cheese is as follows. — The rennet is put into the milk as soon as it is taken from the cow when coagulated the hand or a wooden bowl is passed gently two or three times through the curd, which is then allowed to stand a few minutes, the bowl or finger is again passed through it and it is permitted to stand some minutes longer. The whey is taken off with the bowl and the curd is put into a wooden form of the proper size and shape of the cheese to be made. This form is cut out of the solid wood by a turner, and has one hole in the bottom. If the cheese is of the small size (about 4 lbs) it remains in this form about fourteen days. It is turned daily the upper part during this time being kept sprinkled with about two ounces of purified salt of the large crystals. It is then removed into a second box or form of the same size, with four holes in the bottom and put under a press of about 50 lbs weight, where it remains from two to three hours, if of the small size and four to six hours, if of the large size. It is then taken out, put on a dry apron shelf in the cheese apartment and daily turned for about four weeks when *Edam* cheese are generally fit to be taken to market. Alkmaar in North Holland is the great market for *Edam* cheese. It is not uncommon to see 800 farmers at this market, and 470 000 cheeses for sale on one day. (*Ibid.*)

**5009 Gouda cheese.** "This kind of cheese is also made from the milk immediately on its being taken from the cow. After gradually taking off the principal part of the whey a little warm water is put upon the curd, which is left standing for a quarter of an hour. By increasing the heat and quantity of the water, the cheese is made harder and more durable. All the whey and water is then taken off and the curd is gradually packed hard into a form, cut out by the turner flatter and broader than the form for the *Edam* cheese. A wooden cover is placed over it and the press with a weight of about eight lb is put upon it. It is here frequently turned, and remains under the press about twenty-four hours altogether. The cheese is then carried to a cool cellar and put into a tub containing pickle. The liquid covering the lower half of it. The water for the pickle is boiled and about three or four handbals of salt are mixed in about thirty Imperial pints of water. The cheese is not put in until the water is quite cold. After remaining twenty-four hours, or at most, two days, in the pickle tub, where it is turned every six hours, the cheese, being first rubbed over with salt, is placed upon a board slightly hollowed having a small channel in the centre to conduct the whey which runs off into a tub placed at the one end. This board is called the *scoutbank* and several cheeses are generally placed upon it at a time. About two or three ounces of the large crystallized salt is then placed upon the upper side of the cheese which is frequently turned the side up; most being always sprinkled with salt. It remains on the scoutbank about eight or ten days, according to the warmth of the weather. It is then washed with hot water rubbed dry and laid upon planks, and turned daily until perfectly dry and hard. The cheese-house is generally sunk during the day but must be open in the evening, and early in the morning. Each cow as grass in Holland is calculated to give about three or four lbs of new milk cheese per day. (*Ibid.*)

**5010 Kanter cheese.** "The skimmed milk is poured out of the stone, copper or wooden milk-dishes, into a tub or tub, in which it remains to settle half a day. About the fourth part is gently poured over into a copper boiler which boiler by the most careful farmers, is oiled with sweet oil, to prevent burning the milk, or giving it a staled taste. This is heated till the hand can hardly bear the heat, and then taken out and mixed with a certain third amount, the whole being stirred about; the rennet is then put in, and when coagulated, the whey is taken out with a wooden bowl, the curd is hard worked and pressed with the hands, and then put into a cloth, the four corners being folded on the top, and the whey pressed out. The curd is next put into a broad tub, called a *portcheble* and hard a *orind*, and trodden upon by the bare feet; for although there has lately been a plan introduced to obviate this disagreeable practice, this is generally the mode used in making common or *Kanter* cheese. The next process is to mix among the curd a ched handful of soft fine salt in every third lb of cheese. The curd is then put into a strong circular form (of staves, and hoops, about three inches thick, with holes bored in the bottom), with the

upon. The screen is composed of two upright posts, twenty-feet in height. Through holes in the upright posts horizontal poles are placed, reaching from one upright to the other. On these poles, the back-wheat and other kinds of fodder are placed. A narrow roof of boards covers the whole, passing from one upright to the other. The sheaves of back-wheat are also sometimes fixed on an upright post. (*Cook's Travels* p. 34.)

601. — *On Wheat* are cultivated in considerable quantities in Carthage and Syria; but in places, they are given to the hogs and cows. (*Cook's Travels* vol. i p. 26.) In Hungary sugar has been lately raised from them.

602. The rural townships of *Schleswig Holstein*, and *Lonsburgh*, has been given at length in the *Journal*, &c., vol. i p. 37 and of the agriculture of Denmark and Sweden by James F W Johnston, F. R. S. in the same work, vol. iv p. 194 at seq.

#### RUSSIA AND POLAND.

603. — 604. *Roads in Poland.* By far the best specimen of that kind of road usually called macadamised, for want of a more expressive term, is to be found between Warsaw and Kalisz, a distance of thirty-three and a half Polish, or one hundred and fifty six English miles. Throughout this distance it is uniformly hard, level, and as smooth as a billiard table quite straight, planted with a double row of trees on each side, and with very tolerable inns at each post station. It is doubtful whether a better road is to be found in England certainly not on the Continent, except, perhaps, between Milan and Cremona, or even as far as Vienna. The Warsaw road is perfectly new, and owes its existence to the grand duke Constantine whose efforts to improve the internal communication of the country in every direction were incessant. One feature of the Polish road in question deserves notice, because it tends to give it the appearance of a carriage-road in a gentleman's park kept in the highest order — namely the manner in which the sides are dressed all along with green turf which looks like mossy banks, cut smooth and perfectly level. This method of flanking a macadamised road that has been cut through hills, or prominent undulations in the ground, offers, besides its neat appearance, a great advantage; for it prevents, in a great measure, the carrying away of the loose earth and detaching of the roots of trees during heavy rains, both which inconveniences, very injurious to the road itself, take place when the sides are not covered with turf. (*Grassie's Russia*, p. 380.)

605. *British Farmers in Poland.* Since the peace of 1814, some Scottish farmers have settled in different parts of Poland, and chiefly in the neighbourhood of Warsaw. The soil and the climate are found much more favourable both for agriculture and gardening, than might naturally be imagined. Though the winters are more severe than they are at Edinburgh yet the summers are much warmer and corn and fruits ripen much sooner and better. The cucumber grows freely and bears abundantly in the open air during the summer months. The estate or farm of Wilga, on the river of that name, a view of which is given in fig. 1140. consists of 1,600 acres, and was purchased by a near relative of the author in

1140

1822. The buildings consist of a dwelling house (a), with a detached kitchen (b), a brewery (c), a distillery (d), a machine for raising water to supply both (e), a corn mill (f), sheds for feeding cattle (g), an ice-house (h), in which ice is kept above ground by means of thick double walls and doors, and large barns, a threshing-machine, coach house, stabling and all other offices, including a carpenter's shop and house, blacksmith's shop and house, miller's house &c. Beside these there is a small colony of cottages for the common labourers. Behind the house there are a large garden and orchard with summer house, green-house, &c. the estate having been the property and residence of a Polish nobleman, considered a man of taste. The situation of this property is about thirty miles from Warsaw, in a fat country and there is good communication between it and that city, both by land and water. The soil is light in most places, but in others it is loamy. About half the surface is covered with wood, chiefly birch, poplar and Scotch pine, which is felled at stated intervals, and is floated down the Wilga and the Vistula to Warsaw where it is sold as fuel. The culture pursued on the arable land is the convertible system of — 1. turnips; 2. corn, chiefly barley and wheat; 3. clover; and 4. oats. The turnips and clover are consumed in the dwelling-house by which cows, or cattle for the butcher. The corn is either ground into flour or malted and brewed into beer or distilled into spirit; for both of which there is an ample market at Warsaw. Butter and cheese are made, for which there is also a great demand. Figs are cultivated, but the Polish towns being chiefly occupied by Jews, and trade of every kind being chiefly in their hands, it is found that pigs cannot be driven to market, and sold there alive as in Britain; but the carcasses are salted, or cured in brine, and sold in that state, to Christian consumers. The fattened cattle are sold by private

contract to Jewish dealers, who dispose of them, either to their brethren in Warsaw, Cracow and other towns in Poland where they are killed in the manner peculiar to the Jews; or to Christian butchers either in Poland, Prussia, or Russia. Husbands are sent to Danzig and other sea-port towns. An unlimited supply of manure may be obtained from Warsaw at present, though it cannot be expected that this will long continue to be the case; but manure is abundant, not only in Warsaw, but all over the country and the supply of this manure will, probably, for many years, exceed the demand. A crushing-mill has been or is about to be added to the corn or flour-mill on the estate. It is also in contemplation to establish a steam-bus between Wilga and Warsaw, which will add greatly to the rapidity of conveyance between the two places. The flour might then be converted into bread, and the cattle, for Christian consumption, slaughtered on the farm. For it is chiefly by unscrupulous farm produce, that it can be at all disposed of to advantage in such a country as Poland. The great drawback to farming in Poland, is the want of moral principle in the labourers, who require continual watching both to keep them at work, and from stealing and drinking; but as this has arisen from the harsh treatment to which as slaves, they have been subject from their masters through many generations (see § 660.) it may be diminished by kindness to the adults, and the education of the children.

800.—*Food of the peasantry in Russia.* Rye bread is the chief support of the peasants in the north of Russia; but, in order to save the rye flour and to make it last the longer the inhabitants, when compelled by necessity mix with it fine ground oatmeal the meal of buck-wheat, and the husks of the wild mustard seed (*Sinapis arvensis*). Brandy is, in general, distilled in Russia from rye meal, with a more or less additional quantity of barley oatmeal and barley malt, but very seldom from wheat, or buck-wheat. The Russians also distil brandy from potatoes, juniper berries, and *Sorbus aucuparia*, at all times with an addition of meal and malt. They distil, in Astrachan, a sort of French brandy from damaged vines, prunes, kernels of cherry-stones, and wild almonds (*Amigdalus amara*). Some of the distillers make use of the skin and stalks of pressed grapes, raisins, and the waste in sugar refineries, with which they make good brandy. To the worst and common sort of brandy belongs the drams of Kamtschatka, or *Horseshoe Sinigdium*, another use by the Kamtschats, made from some distilled mare's milk, which is spirituous but rather of a disagreeable flavour (*Ann. Board. Agr.* vol. i.)

806.—*Agriculture in Livonia.* The country before reaching Volma, offers a tolerable specimen of the present state of agriculture in this part of Livonia. Forests, both old and new in considerable numbers, are met with here and there, succeeded by corn-fields; barren heaths; farm-houses consisting of one or two wooden buildings, and a yard, in tolerably good condition; small horses, and diminutive bearded cattle, no inclosures, except a kind of palisade, marking the divisions of property or enclosing the farm-houses from intrusion, and extensive buildings serving as granaries to hold the crops. These are the most prominent agricultural features of the country. The Livonians have the reputation of being good farmers. (*Greenwell's Russia*, p. 307.)

807.—*Agricultural products of Russia.* The hop is indigenous in the district of Petersburg; a few are also cultivated in gardens, and the crop gathered the end of September. Hemp is sown about the middle of May and pulled in the beginning of September. Flax is sown in the beginning of June and pulled in the middle of August. Both these plants are grown only in small quantities for private use. Red clover is sown along with barley and oats, and cut the following year, about the end of June, and the second in September; the plants are frequently destroyed by the early frosts. The *Silene* plants grown in the district of Petersburg are the following:—Some winter wheat sown upon good soil sown in the latter end of August and the beginning of September is reaped about the middle of August. Spring wheat is sown on newly cleared lands in the beginning of May and reaped about the middle of August. Rye is sown more extensively than any other grain, on most descriptions of soils and in the latter end of July and the whole month of August. It is reaped the latter end of July and the beginning and middle of August. Spring rye is sown upon high and sandy ground in the beginning of May and reaped the latter end of August. Barley is sown in the beginning and middle of May and reaped about the middle of August. Oats are sown the latter end of April and beginning of May and reaped from the middle of August to the beginning of September. Buck-wheat is sown upon high sandy lands in the month of May and reaped in the beginning and middle of September. No elegant plants are cultivated except the cucumber and the white mustard in a few gardens. The following are the leguminous plants of the same district:—White and gray peas are sown in the beginning of May gathered green the latter end of July and ripe the latter end of August. Beans are sown in the beginning of May and reaped in the middle of August; French beans are sown in gardens but they seldom do much good. (*Ann. Board Agr.*, vol. i.)

## SWEDEN

808.—*General appearance of the country in Sweden.* A bishop of Bergen is said to have given the name of Northern Italy to some districts of Norway and Sweden. The pine forests are very beautiful, especially when the pale green of the young shoots contrasts with the older foliage. From the appearance of some of these trees on lofty cliffs, it is easy to perceive how in alpine countries the descent of the roots of the pine and the mountain ash through fissures, contribute to the splitting of the rocks. The Swedish mistletoes are raised on plinths to keep them above the snow. The roads, winding through extensive pine forests are picturesque in the extreme. (*Brooke's Travels in Sweden*.)

809.—*808.* The cottages of the peasantry in Norway have double roofs. This additional protection renders them warm and secure against the blasts of winter. The manner of building these cottages is the same as in Sweden, and on the roof of each a luxuriant crop of grass was generally growing, though some were loaded with a thick coating of pebbles, and above them were two or three large fragments of rock, to secure the whole from being blown away by the winter storms. (*Brooke's Travels*, p. 106.)

809.—*804.* Slacks for drying newly-cut corn are also used in Sweden. They are generally made of young pine trees, eight feet long about one inch and a half in diameter at the top, and four inches at the bottom. Both ends are pointed and the thick end is let into the soil by the aid of an iron crowbar. The first sheaf is put on the stake with the root ends of the corn downwards and the other sheaves, to the number of fifteen or sixteen, are placed in an inclining position. (*Quart. Journ. Agr.* vol. iii p. 688., and Professor Johnston in *Journ. A S E* vol. iv p. 196.)

## BRITAIN

805.—*800.* The progress of agriculture in Britain, more especially in England, since the second edition of this Encyclopædia was published in 1821 has been singularly rapid though it must be acknowledged that it has hitherto been more in the direction of discussion than of actual improved practices; the introduction of the latter requires time. The first great stimulus to agricultural discussion in England appears to have been given by the Report to the Agricultural Committee by Mr Shaw Lefevre, which was printed in 1836. In this Report the frequent drain system introduced in Scotland by Mr Smith, of Dunsinon (§ 639), is mentioned as capable of reclaiming every acre of cold wet land in the country, and raising it in a short time to a par with the very best soils. According to Mr Lefevre's idea, if this system was applied, whether with or without a corn ley, the produce of Malton would become so abundant, that there would be no danger of prices rising for half a century to come. Mr Lefevre counsels the British agriculturist to accede to a total repeal of the corn laws and to stand on the field of free competition with all the world; trusting to his improved skill and improved means, to his capital, and to the aptitude of the soils of his country for improvement, to enable him to do so.

In two years after the publication of this report, the Royal Agricultural Society of England was formed; partly from the increasing interest taken in agriculture by the landed proprietors, but principally from their having observed and remarked on the great good effected by the Highland and Agricultural Society of Scotland. The idea of the Agricultural Society of England was first suggested by Lord Spencer at the dinner after the show of the Southfield Club in the beginning of 1838, and a meeting was held for that purpose on the 8th of May following, when the foundation of the Society was laid. Its progress since has been so extraordinary, that it now reckons upwards of 7,000 members, including all the great landed proprietors of England. The society holds annual meetings in different parts of England, as the Highland Society does in Scotland, and its journal, which is published quarterly, contains a great number of valuable communications from scientific men and unlearned landed proprietors. The desire for scientific knowledge, mainly brought about by the British Association for the advancement of sciences, has called forth several eminent chemists who have directed their attention to agriculture; and to this the British Association have taken a prominent part. It is to this Association that we owe the volumes of *Lights on Vegetable and Animal Chemistry*, which have thrown so much new light on the subjects of which they treat. The establishment of a Professorship of Agriculture in Oxford, and one also in the University of Durham, have seconded the efforts of the Agricultural Society and much good continues to be effected by the model farms on the estate of Lord Ducie, in Gloucestershire, and by the lectures of Professor Henslow and his exertions in various ways among the farmers of Suffolk. In a direct and practical view perhaps the greatest service to agriculture, next to the frequent drain system, has been the introduction of new substances as manures, or the more frequent use of such as were previously little known. Among these may be mentioned bones, guano, gas liquor and a variety of saline substances, all of which, under particular circumstances, have been found to add materially to the produce of the soil. The Agricultural Society of England, like the sister society in Scotland, have wisely shunned from experimenting themselves, but have offered ample prizes for experiments made by others, and Professor Henslow has drawn up a scheme (detailed in his *Lecture to the Farmers of Suffolk*, 1842, 8vo.) by which the same experiment may be repeated in any number of places all over the country. Excellent works on the Chemistry of Agriculture have been published by Professor Johnston, of Durham, Mr. Schly the Professor of Chemistry to the Horticultural Society and important essays or treatises on some departments of the subject with reference to Agriculture, by Professor Danksley, Dr. Madden, Dr. Lyon Playfair, Mr. Trimmer, Mr. Johnson, Mr. Lybourn and others, and the stimulus given by these works and the societies mentioned, has given such an impetus to improvement, that there can be no doubt of its rapid progress for a long period to come.

8063. In Scotland, though the agriculture is far in advance of that of England, yet advantage has been taken of the new manures; and the point in which the country was most deficient the breeding of domestic animals, has received general attention, and the consequence has been great improvement in this department.

8063. Ireland has established its Royal Agricultural Society which continues the exertions begun in 1821. No one has contributed more to the improvement of the agriculture of small farms in Ireland than Mr. Blacker, of Armagh, whose essays on the subject ought to be in the hands of every proprietor in Ireland. (See Catalogue, and also G. J. A. vol. v. p. 385.)

8064-807. In the literature of Agriculture, as it may be supposed, considerable progress has been made since 1831. The *Mark Lane Express* is the most popular farmer's newspaper in England, but we have also the *New Farmer's Journal*. There is no paper of the kind in Scotland, but in Ireland there is the *Farmer's Gazette* and *Journal of Practical Horticulture*, a very excellent weekly paper. In England we have the *Farmer's Magazine* the papers in which generally appear first in the *Mark Lane Express*, the *British Farmer's Magazine*, and the *Journal of the Agricultural Society of England*. The only agricultural periodical in Scotland is the *Quarterly Journal of Agriculture* which continues to maintain its high reputation. For the other works published since 1831 we must refer to the Catalogue in continuation of that given in the *Bibliography of British Agriculture* p. 1205. As this Catalogue is arranged in the order in which the works were published a glance over it will form a very good chronological history of agriculture from 1831 to the present time.

#### ASIANIC TURKEY

8066.—821. On the agriculture of Asia Minor some interesting notices will be found in the *Journal of the Geographical Society* vol. x. It appears that on the banks of the Lake Van, the drill husbandry has been practised from time immemorial, with rude, but yet ingenious implements.

#### PERIA

8038.—864. The general appearance of the country in Peria is characterized by its chains of rocky mountains, its long arid riverless valleys, and its still more extensive salt or sandy deserts. The northern provinces form an extensive table land which rises from a lower plain and is interspersed with numerous clusters of hill chains of rocky mountains, and barren deserts. The lower ground under the name of *Duchistan*, or the level country exhibits a succession of sandy wastes, where the eye is occasionally relieved by a dark plantation of date trees and a few patches of corn, in such places as are blessed with a freshwater rivulet or a copious well. On the banks of the Tigris this tract becomes more fertile. Wherever water abounds vegetation is most luxuriant, but the country generally suffers from excessive drought. The mountains present masses of grey rock, and the only trees that are found in abundance are the tall poplar and stately cypress (*Platanus orientalis*) and the fruit trees which surround every bowl. These bowls are clean and comfortable and wages are high while food is cheap. (*Fraser's Peria*, Edin. Cal. Lib. vol. xv.)

#### INDIA

8087.—808. To give some idea of the present state of agriculture in India, Mr. W. Carey one of the missionaries active in the Transactions of the Agricultural and Horticultural Society of India, vol. i. part 1. 1813, that, in many parts of the country the same crop is invariably raised on the same ground year after year. Hay is never cut till the grass has died or withered on the ground. scientific rotation of crops is a subject to which Indian cultivators are strangers and the manure produced by animals is generally consumed for fuel. No attempt to improve stock appears ever to have been made in India though there is every reason to believe that all the animals used in the husbandry of Europe are capable of as high a degree of improvement in India as they are in more temperate regions. The quantity of waste lands in India is said to be so large as almost to exceed belief. Extensive tracts on the banks of numerous rivers are annually overflowed, so that they produce little except long and coarse grass seldom turned to any useful account. During the rainy season, these tracts are the haunts of wild buffaloes, which in the night come up from them and devour the crops of rice on the high lands. In the cold season wild dogs, tigers, and other voracious animals, mangle with the buffaloes in consuming these extensive tracts of diluvial soil which, though now so pernicious, might, by embanking and draining, become the richest lands in the country, and contribute greatly to the improvement of the climate. Similar observations might be made respecting numerous tracts now wholly covered with wood, and producing nothing whatever to civilized man, but, as the country proving a nuisance to the surrounding districts by affording a shelter to vicious animals. The oppression of landowners, and petty efforts, on the cultivator is so great that in some parts of the country no farmer can reasonably promise himself success.

city for a single night. Thus, concludes Mr. Carey, "one of the finest countries in the world, owning almost every variety of climate and situation, dissected by hills and valleys intersected in every part by streams (most of which are navigable six months in the year, and some of them through the whole year afford every facility for carrying manure to the land, and every part of the produce to market), is, as far as respects its agricultural interests in a state the most abject and degraded." (p. 50.) This is a most startling picture; but it is incident to the countries in a particular stage of their progress in civilization. Thus was when the low districts of England were ravaged by the wolves and hares from the mountain forests, and when the crops on the alluvial lands of her rivers were actually swept away or at least greatly injured, by floods. As to the crops, by reporters and travellers from others, there will always be abundance of such evils, till mankind are brought to something like equalization in point of knowledge, and consequently power. In short, the mass of society become fit for self-government. (From *Ag. Soc. of India*.) The potato has at length been effectually introduced into India, and as good potatoes are to be had in Calcutta as in London. Baron Bihal introduced them into Cashmere and Little Tibet. (C. C. 1844 p. 607.) A copious account of the agriculture of Hindostan, will be found in the *J. A. Soc.* vol. viii. p. xi.

# ANTHRA

1838.—1837. The whole territory of New South Wales Dr. Lang, writing in 1834 informs us is divided, like that of Great Britain into counties and parishes, but these divisions are scarcely ever referred to in the common intercourse of colonial life. Except in government deeds or legal documents the grand natural divisions of the country are the only ones recognized by the colonists. These divisions are the districts of the Hawkesbury, of Hunter's River, of Bathurst, of Illawarra, and of Argyle. The district of the Hawkesbury which is let out in small farms of from 30 to 100 acres each, has been long considered the granary of the colony from the extreme fertility of its soil though the system of agriculture practised in it is as slovenly as can be well imagined. The surface of the ground is for the most part merely scratched, and nothing like a proper rotation of crops is ever dreamed of. Wheat year after year for twenty years together and sometimes wheat and maize in succession of the same ground during the same year is the barbarous system of husbandry that prevails on the Hawkesbury. The district of the Hunter's River is let out in farms of from 500 to 2000 acres each. Dairies are frequent throughout this extensive district and large quantities of butter and cheese, of superior quality, are forwarded regularly by the steam boats to Sydney. The vast plains of the B. district are chiefly tenanted by black cattle and sheep and the farms are generally 2000 acres each. This may be considered the wool district. The cultivated land of the Argyle district is almost all in pasture but there are interspersed extensive tracts of the most barren country imaginable. The district of the Illawarra consists of a narrow strip of arable land of the first quality let out to small settlers, who cultivate grain, potatoes, pumpkins, &c. for the Sydney market, their produce being conveyed to the capital by water in small coasting vessels of great numbers. This is also the timber district, great numbers of the red and white cedar trees growing here and that wood being generally used for cabinet and joinery work all over the colony. Besides these there are several large tracts of pastoral and alluvial land which cannot be properly classed in any of the above-named districts and a very great extent of country remains unpeopled. The rich alluvial land on the banks of rivers is called interval land. It is very productive but is difficult to clear. Norfolk Island has a soil of the same vegetable mould even to the tops of the highest hills and appears well adapted for the culture of coffee. If not sugar, it is now (1834) occupied as a penal settlement for the colony of New South Wales. (Dr. Lang's *Natural and Statistical Account of New South Wales* vol. i.)

1839. General aspect of the country. The principal town Sydney is beautifully situated on Sydney Cove one of the most beautiful inlets of Port Jackson about six miles from the entrance of the harbour. The headlands at the mouth of which constitute one of the grandest and most interesting features in the natural scenery of the country. Many of the most interesting localities on the shores of Port Jackson between Sydney and the headlands are in the hands of private proprietors. On Woolloomoolli or Hill (fig. 1141) which is an elevated projection of the land about a mile from Sydney most of the officers of the colony have houses. The second town of the colony is at present Parramatta but Maitland will probably soon supersede it as the latter place is situated at the head of Hunter's River in the centre of the most extensive agricultural and grazing district in the colony. Between Sydney and Maitland there are two steam boats and a company has lately been formed called The Hunter River Steam Navigation Company. With the exception of the large open plains in the interior of the country the territory of New South Wales is in its natural state one vast forest. On the banks of the rivers and especially on the alluvial land within the reach of their inundations this forest becomes what the colonists call a thick brush or jungle. Immense trees of the genus *Eucalyptus* such as the string bark, the Blue gum, &c. *Myrsine*, and the Iron bark, &c. *Acacia* tower upwards in every direction to the height of 150 or 200 feet while the cedar and other trees of inferior elevation with innumerable wild vines and other parasitical plants fill up the interstices. In the sterile regions the trees are stunted in their growth and of a most forbidding aspect, their trunks and naked branches being frequently blackened by the action of fire as in the Bushy Plains. The soil of these regions is a white sand and nothing can exceed the loneliness and desolation of the scene. (Ibid.)

1840. The settled portion of New South Wales. In 1833, Stuart tells us extended from the 25th to the 32d parallel of latitude. The population of the colony is said to consist of 49,000 free settlers, and 26,000 convicts. Its imports in the year ending January 1838 amounted to £55,000 of which 144,705/ was the value of commodities imported from foreign states the rest being the produce of Great Britain and her colonies. The exports amounted to £61,244/ of which £1,048,000 consisted of British and foreign merchandise re-exported and the remainder was the produce of the colony the New Zealand fisheries and the South Sea Islands. The chief articles of export which were shipped to the western country were — New Zealand flax, 805 tons value 15,362/ sperm and black oil 3166 tons value 149,921/ and wool 1,011,150 lbs value 78,407/. In 1831, 100 less than 100 vessels entered the harbour of Port Jackson from foreign ports the amount of their tonnage being 31,260 tons. (Stuart's *Report drawn into the Interior of Australia*.)

1841.—1838. The mineral productions. Marble of a good quality and which takes a beautiful polish has been obtained in Argyle. In one part of its course Hunter's River flows for a considerable distance over rocks of jasper and beautiful agates, opals and chalcid ivory besides innumerable petrifications, are found on its banks. (Hunt and Sturt's *Account*, &c.)

1842.—1840. Natural productions of New Holland. A peculiar character is given to the woods of the extratropical parts of New Holland and to the woods of Van Diemen's Land, by the species of trees of the order *Proteaceae*. These are numerous and the leaves of the generally of them have a vertical position, and a similar sacc on both surfaces. These surfaces have insensate stomata are distinguished by a reticulation of the fine veins of the leaf into numerous small compartments or areolations within each of which on one face of the leaf and very generally on both faces is lodged a minute gland. (See *Brown's Supp. prim. Flor. New Holl.*)

1843. The vegetable productions of New Holland. Some of the most common trees in the neighbourhood of Sydney are several of the different kinds of *Eucalyptus* which is there generally called the honey-suckle (*Banksia integrifolia*), the apple tree (*Angustifolia imbricata*), the forest oak (*Casuarina torulosa*), and the gum tree (*Leucocarpus arborea*). The last is particularly beautiful. There are also the broom (*Jackabara scoparia*) which is called the dogwood at Port Jackson and the wood of which is very difficult to burn and the tea tree (*Malaleuca laurifolia*). The name of the tree is given

almost indifferently to several kinds of *Neolobos* and *Leptocarpus*, because it is supposed that the first colonists made tea from the leaves of some of the species of these genera. The leaves blue, red, or white gum trees, as applied to different species of the genus *Eucalyptus*, refer to the colour of the bark. The wood of trees of this genus is very durable as a proof of which, Dr. Lang informs us that a stump

of a species of *Eucalyptus* (blue gum tree) remained quite sound for thirty-five years in the ground, after having been cut down. When it was necessary to remove it, it took a fortnight to burn out the root. The circumstances of this trunk resembling a blue sound, for such a long length of time is very remarkable, and reminds us of what DeRoche states respecting the stumps and roots of the silver fir (Bard. Mag., vol. x, p. 459) viz., that they will continue to live and even grow during a great number of years after the tree has been felled (*Lang's Hist. and Statist. Account*).

1844-1841 Agriculture in Australia appears to be making considerable advances, from the more frequent influx than formerly of emigrants with capital. Some Scotch farmers have settled in the interior of New Holland a good many have located themselves in Van Diemen's Land and there are some even on the Swan River. In 1820, the Cashmere goat was imported into the colony by Mr. Riley and about the same time a Cornish grower sent Mr. Riley back with him from England established vineyards in different parts of the country which from accounts received in 1844 have already produced wine (*See Gard. Mag.*, vol. x, p. 189).

1845 The principal agricultural products of New South Wales are wheat and maize. The cost of clearing heavily timbered alluvial land is about £1 an acre but sometimes a single crop of maize clears the expense. The return of wheat varies from 15 to 40 bushels an acre and in the Argyle district it has reached 45 bushels but the system of husbandry is generally speaking wretched in the extreme. The staple article of Australian produce is wool of which Dr. Lang says 1,515,186 lbs., and Sturt, 2,500,000 lbs. were exported in 1835. It is generally supposed that John Macarthur was the first to introduce fine-woolled sheep into the territory and though the honour is also claimed by another individual there is no doubt that Mr. Macarthur had the merit of having demonstrated their adaptation to the climate, and the capability of the colony to produce wool to almost any extent. This has been effected in comparatively a very short space of time. About 1793 Mr. Macarthur commenced sheep farming and in a year or two he had an opportunity of crossing his coarse fleeced sheep with merino blood. So prolific was the mixed breed, that in ten years, a flock originally consisting of not more than seventy Bangal sheep had increased to 4000. In 1808, Mr. Macarthur went to England carrying samples of his wool which was so much approved of by a committee of manufacturers, that government were induced to encourage him in his attempts to produce fine wool in the colony by directing that he should receive a grant of land for that purpose, in the low pastures, which is now named the district of Capetown. In 1808, Mr. Macarthur returned to New South Wales with two ewes and three rams, purchased by him from the worsted flock of George III. his flock was removed to the low pastures, and soon that period, the wool of New South

Wales has been rapidly increasing in value in the home market (*Dr Lang's Hist. and Statist. Account, and Stuart's Report, into the Interior of Australia.*)

1044. *Fruits and other vegetable products cultivated in the colony of New South Wales.* These, which are the most important of the fruit bearing plants to a young settlement, have only been cultivated a few years to any extent. "There are now however many acres of vineyards throughout the country," and wine and brandy have been manufactured from grapes grown by Mr. Macarthur's sons at Camden. The wine is very similar to the light wines of France and Germany. Tobacco has been grown to great extent, particularly on the rich alluvial lands, and is only inferior in point of manufacture. Olives, hops, indigo, and opium, are beginning to be cultivated: the castor-oil tree (*Ricinus communis*) grows luxuriantly and oranges and all the genus *Citrus* and figs and peaches, bear abundantly. The hedges to the fields are generally formed of guinea or lemon trees. There are several orange orchards, producing annually from 12,000 to 20,000 dozen each. The fruit of the loquat (*Eriobotrya japonica*) is sold in great quantities to the Sydney market. Cotton, coffee, tea, and sugar have been tried and found to answer though their cultivation has not yet been attempted on a larger scale. (*Hist. and Statist. Account, vol. i. p. 378.*)

1047.—1042. *As a country for emigrants.* During Sir Thomas Brisbane's administration any respectable person who pledged himself to government to maintain and employ ten or twenty convict servants, could obtain 100 acres for each such servant. This occasioned a great demand for convict labourers and, instead of government being obliged to establish penal settlements in order to employ them, there was, during the government of General Darling, applications for no fewer than 2000 convicts lying unsatisfied at the office of the principal superintendent of convicts. "There is no doubt that New South Wales is an excellent country for the agriculturist, but it is subject to some drawbacks. A season of drought, which continued three years, began in 1827 and it appeared from the statement of the natives, that the country was subject to periodical visitations of that nature. It is also subject to inundations, particularly from the Hawkesbury River. From the imperfect state of husbandry throughout the country and the fertility of the soil, much may however be done by an experienced agriculturist. For eight months in the year, from March to November, the climate is delightful, but during the Australian summer, the heat is considerable. The most unpleasant part of the year is during the prevalence of the hot winds. These winds occur on an average four times every summer and continue from ten to four to thirty-six hours at a time. "The atmosphere feeling like a current of heated air from a furnace, and the thermometer generally standing at from 90° to 100° and sometimes even reaching 118° of Fahrenheit. The extreme dryness of the air, however, prevents this degree of heat from being so insupportable as it would be in a moist climate like England. The hot wind is generally succeeded by a violent gale from the southwest and very often by a shower of hail. (Vol. ii. p. 184.) Very few persons live to attain old age, but they generally enjoy excellent health and spirits while they do it. In short, observes Dr Lang "the lump of life in the malarious climate of New South Wales is like a taper immersed in a vessel filled with oxygen gas. It burns more brightly than in the common air, but it is sooner extinguished. To persons possessing property to the amount of from 1000*l.* to 5000*l.* New South Wales presents a most eligible prospect for affording a comfortable settlement. They may put out part of their capital at interest for ten per cent. on excellent security and 1000*l.* will not only purchase 1000 acres of land at 1*l.* an acre (the selling price in 1822) but will be amply sufficient to stock it." (*Lang's Hist. and Statist. Account, vol. ii. p. 300.*)

1048.—1044. *Van Diemen's Land.* This colony may be considered as the most prosperous in Australia, and the suitability of its climate for Englishmen is very far more and more confirmed. The colony, Mrs. Frisnap observes (*Journal of a Voyage from Calcutta to Van Diemen's Land*) contains every source of wealth and health to short every thing but money. Interest on mortgages with the very best securities is 15 or 20 per cent. Bank shares pay 16 per cent. There is no immediate prospect of any check to that rise in the value of land which is now observable. Money well invested in land here and allowed to accumulate, will be tenfold its original value in fifteen years. 500*l.* would purchase a noble property here. 1000*l.* will buy a fine, healthy and beautiful estate of 1200 acres, 500 of them already in cultivation, and the whole becoming more valuable every year. Corn and potatoes are exported to Sydney and wool to England. Wool averages 6*d.* per pound. The whole colony is on the ad and and its resources remain to be developed. Fresh lands are granted in square miles in the proportion of the square mile, at 540 acres for every 500*l.* sterling of capital, which is the largest grant that is made to any settler without purchase, as the smallest is 500 acres. The total territory is acres in 15,000,000 of which about one half is rocky or thickly wooded the rest arable and pasture, the proportion of arable being as one to six of pasture. The total number of acres granted to individuals, up to December 1826, is 1,323,423; consequently there are 15,676,577 unlocated acres.

1049. The soil of *Van Diemen's Land* is of peculiar softness, and, from the greater attention now paid to cleaning and picking the price is rising. Wheat is of a very superior quality weighing generally about sixty and sometimes as much as sixty five pounds per bushel. Oats are beginning to be raised. Barley has not yet succeeded, peas, and other species of pulse, are plentiful. Skins are also valuable seal-skins the most so, being worth about 2*l.* each in England. Kangaroo skins are essentially useful in the colony for hats and also for shoes, which are remarkably durable when well packed, and of a good size, these skins fetch nearly 6*d.* a pound in London. Shoemakers make 100 per cent on the raw material. (*Cape of Good Hope Lat. Gen., vol. iii. p. 137.* see *Bachhouse's Narrative of a Visit to the Australian Colonies* 1843, 1 vol. 8vo with maps and etchings.)

1050.—1054. *New Zealand*, from its climate which resembles that of the south of England, from its soil which is in most places good, and from the inhabitants, which may be described as at least half civilised; appears to be one of the most desirable countries in the world to which a native of Britain can emigrate. (See *Backhouse's New Zealand*, 1843, 3 vols. 8vo. *Geogr. Chron.* 1840, p. 99. *Gard Mag.* 1842, pp. 128 and 226; and *Bulwer's Emigrants's Handbook of Facts concerning Canada, New Zealand, Australia, Cape of Good Hope &c.* 1842, 1 vol. 11mo.)

#### EGYPT

1051.—1077. *Egypt, under the government of the present pasha*, is undergoing extensive political improvements, among which agriculture, Mr. St. John observes, is not altogether forgotten. The culture of cotton has been commenced on a large scale by government; and an extensive tract of country round Cairo, which was long rendered useless by prodigious mounds of rubbish many of them exceeding seventy feet in height, has been cleared, the mountains having been levelled, and planted with olive trees, which here fruit the second year. The silk tree has been introduced from India, and is found to thrive near Cairo as well as in its native country. The mango, the pine-apple, and other tropical fruits, have been tried and there is an English garden of extensiveness under the direction of Mr. Tyrell, an English botanist. On the whole, there can be no doubt, that, if the present comparatively liberal policy of the Egyptian government be continued for another generation, the face of the country, and the condition of its inhabitants, will be entirely changed. Nature has supplied an excellent soil, and abundance of water, under a climate well adapted for to mature the fruits of tropical countries, and yet not so much as to prevent the grains of temperate regions from being profitably cultivated. (*Egypt and Mohammed Ali* p. 443.) In Dr. Bowring's *Report on Egypt*, presented to parliament in 1840, that country is shown to be making gigantic strides in civilisation, through the efforts of the present pasha, Mohammed Ali. Agriculture is improving, though not very rapidly. The principal agricultural products of the country is cotton, corn, beans, barley, peas, and various other seeds. Watering is an essential element of culture

and by means of it the soil, which in many places is excellent of itself, is made to produce enormous crops. The various details of Egyptian agriculture, as extracted from Dr Bowring's Report, will be found in the *Gardener's Magazine* for 1844, p. 614, to 655.

#### MAOROOS.

1864.—1865. *Agriculture in Morocco.* The farmers plough and sow at the same time. The ploughing is performed by one man, who, while he guides the plough, which has a single handle, with his right hand, holds the reins, which are made of the palm-leaf twisted, and a long, thin, pointed stick to goad the oxen, in his left. When he sows, he leaves the plough, scattering the grain very sparingly with his right hand, and harrows it in by passing the plough again over the surface, the furrows being straight, narrow and very shallow without any ridge. The ploughshare has merely a simple tip of iron, which is taken off when the husbandman ceases to work, to prevent its being stolen. (*Brooke's Travels in Spain and Morocco*, vol. i. p. 308.) Some account of the progress of agriculture in Algiers will be found in the *G.*, 1843, p. 47.

#### CAPE OF GOOD HOPE.

1803.—1813. *Albany.* At the close of 1803, when this new settlement was hastening to dissolution the consciousness of equity reversed certain political evils, and the country at once commenced a march of success, which John Candler's Chase believes "the most unparalleled in the history of colonisation." In August, 1803, the Caffre trade, chiefly in ivory amounted to about 34,000*l.* annually, and the exports increased from 20,572*l.* their amount in 1802 to 51,200*l.* their amount in 1803. Hides, horns, skins, tallow, butter, added provisions, and ivory, formed the principal items. Cultivation is extended. Oats, barley, and cut-hay are the chief commodities; wheat has also been raised, and Indian corn, fruit and vegetables grow here luxuriantly. Cattle, sheep and horses are abundant, and every necessary of life is extremely cheap. There are about 24,000 sheep, the wool of which sells at upwards of 1*s.* per pound. Graham's Town has increased from 22 houses to 600, and eight villages eleven places of worship, and fifteen schools have been built. Hat, blanket, and tile manufactories, numerous ironworks, three water and six wind mills, two tanneries, and two breweries, have been established. There is an infant school, a savings bank, a public reading room, and a commercial hall. A newspaper was commenced in January 1804, and it is prospering. The population, in 1833, was 9913 and, as a proof that the country is favourable to human life only 34 out of 245 persons, who landed in 1802 had died in 1830. Such says Mr Chase, is the result of thirteen years' settlement, nearly five of which were those of failure and distress. From what has been related, it may be seen, whether success has attended the efforts of the immigrants or not, their only difficulty in as far as my own knowledge goes, is that of a want of additional labourers to gather in the harvest of growing prosperity; and, as a proof of this want, I refer to the many and frequent appeals to the home government, successively made since 1826, for a new emigration." (*The Cape of Good Hope Ld. Gm.* vol. III. p. 181.)

#### AMERICA.

1804.—1813. *Climate of North America.* Over the whole extent of North America, it is universally admitted that the clearing of the country has modified the climate; that this modification becomes every day more manifest: that the winters are now less severe, and the summers less hot; and, in other words, that the extremes of temperature observed in January and July annually approach each other. (*Jones's Jour.* Apr. 1804.)

1805.—1810. *The soil of the United States is adapted to almost every species of culture.* Wheat grows every where; and tobacco hemp and flax between the Potomac and Roanoke and Mexican Gulf. All the grains flourish in the valley of the Mississippi; but it is particularly in the delta of that river (which, like that of the Nile, is the work of the waters) that the sugar-cane and indigo succeed best. Almost every where, the earth abounds in pasturage, but is not adapted to the growth of fruit trees, or only produces fruit tart and without flavour. The most productive kinds of culture are those of colonial articles and vegetables, a species of cultivation for which the Americans are indebted to the French of St. Domingo, who have taken refuge among them. They are also indebted to them for some seed and kernel fruits. The territories of the United States, with regard to agriculture may be divided into two parts, perfectly distinct from each other. The lands bordering on the Atlantic are generally bad or middling, but those on the other side of the Alleghanies, in the bosom of the St. Lawrence and the Mississippi are not excelled by the best lands in Europe; and have, besides, the advantage of being nearly all virgin, and easily cultivated. Vegetation is hardy but prompt, which is occasioned by the humidity of the soil. (*Beaufort's Sketch of the United States*, p. 81.) From the increase in the number of agricultural periodicals in the United States, the progress of the art would appear to be as rapid as it is in any part of Europe. Sugar has been extracted from the maize, to such an extent as to become an article of commerce, and Mr. Colman, who has been deputed by the state of Massachusetts to make an agricultural tour in Europe, has stated as his opinion to the Royal Agricultural Society that the process of extracting sugar from the maize might be carried out in England with as much success as in America. (*Mora Chron.* June 23d, 1843.)

1806.—1813. *Climate of the Canadas.* John Young asserts, "that, 2000 years since the climate of Europe was precisely similar to that of British America at the present day; in support of which he quotes many authors of antiquity. He attributes the change, first, to the extinction of the forests and the draining of the meadows; secondly to the increase of population, and consequent evolution of animal heat, and the warmth communicated to the atmosphere by the fires within the houses, thirdly to the extension of villages, the process of putrefaction alone generating considerable heat. (*Brit. Forw. Mag.* vol. vi. p. 186.)

1807.—1810. *Emigration to British America.* Mr Ferguson who visited Canada in 1821 says "that Upper Canada certainly is blessed with all the solid appearance of human happiness independence and comfort." The notes of this gentleman are given at length in the *Quarterly Journal of Agriculture* vol. II. and will deserve to be consulted by all emigrants in a work on *Emigration to British America*, by John H. Greaser Esq., published in 1831. The British possessions in North America are stated to be the Island of Newfoundland, Cape Breton, and Prince Edward Island; the province of Nova Scotia, New Brunswick, and the Canadas; the region of Labrador and the territory west of Hudson's Bay. Newfoundland bears a striking resemblance to the Western Highlands of Scotland, and is chiefly adapted for the rearing of cattle and sheep. Prince Edward Island possesses an excellent climate and soil, and is, taken altogether a most desirable spot for emigrants. The society in the island is good, and the inhabitants consist of Europeans from all nations, but particularly from Scotland. Cape Breton is a small island, peopled by between twenty-five and thirty thousand souls, chiefly from the Western Highlands of Scotland. The climate, though humid, is salubrious; the general aspect of the country resembles that of mountainous, and covered with forests, and the valleys contain extensive tracts of excellent soil. Nova Scotia is an extensive country fitted to receive "thousands, perhaps millions, of emigrants." The winters are severe, but the air at that season is generally dry. The peninsula abounds with extensive fields of corn, with timber, with sheep, and it is believed, with root crops. New Brunswick has a climate particularly suited to the cultivation of Britons. The country is covered with numerous forests of evergreen and deciduous trees, and it is everywhere intersected by rivers fit for navigation.

garden. Cacti, trees, pyramids and sundials abound. The Canada includes an extensive territory with a climate which is on the whole salubrious. The thermometer, in summer, rises as high as 80° in the shade, and in winter sinks below zero. The winter in Lower Canada is two months shorter than that of Upper Canada. The geology of Canada is little known; the principal rocks appear to be trap and limestone. There are soils of every description, but the largest tracts are either alluvial, or of a lighter character, approaching to sand. Labrador and the territory west of Hudson's Bay Mr. M. O'Grady does not consider as suitable to emigrants. We can only refer the reader, who is desirous of emigrating, to Mr. M. O'Grady's book, or to a very copious abstract of it which will be found in the *Quarterly Journal of Agriculture* vol. III. p. 380. to 394.

1896.—1897. The culture of wheat in the West India Islands may be mentioned as a comparatively new agricultural feature. The kinds which succeed best are the summer varieties, which have been cultivated to advantage in Jamaica, Barbadoes, and several other islands. Great exertions have been made with a view to introduce the best varieties into these islands from Europe, and to make known the success which has attended their culture by Dr. Hamilton of Plymouth. (See *Gard. Mag.* and *Gard. Chron.*)

## PART II.

### AGRICULTURE CONSIDERED AS A SCIENCE AND AS AN ART (p 208)

1899.—1885 The present state of agricultural science has been treated of in a prize Essay by Dr. Madden, published in the *Hort. Sociey's Transactions* in March 1885, from which we take the largest and most comprehensive view of the subject, we submit the following abridgment.

To the question "What has science done for agriculture?" Dr. Madden answers that scientific agriculture has been investigated by an extremely limited number of individuals, and this chiefly since the commencement of the present century; that a great drawback to the advance of agricultural science is to be found in the want of confidence in it of practical men; and that among practical men there is a great want of scientific knowledge.

"If by the question, 'What has science hitherto done for agriculture?' we are to understand which of the new improvements owe their origin to scientific investigation, we feel obliged to confess that as yet we know of none extensively in operation. But if on the contrary we are to understand it in the wider sense as requiring an account of what science has effected towards establishing agriculture upon a sure basis so that the farmer may be enabled to apply his practical knowledge in whatever situation he may be placed, and will be at once capable of determining what changes in his arrangements, &c. will be necessary if called upon to change his farm so that his operations will no longer be so much the sport of chance that each farmer can be considered as knowing only the treatment fitted for his own farm, we can confidently assert that much very much has been accomplished; and although there is no point upon which we have as yet by any means perfected our knowledge, still there is scarcely any upon which science has not already thrown sufficient light to enable those, who are at all capable of appreciating her services, to derive great benefit and direction in cases of difficulty. To prove this, he takes a general view of what science has effected under the heads of 1 Soil; 2 Effects of Vegetation upon soil; 3 The Art of Culture, and 4 The Economy of Husbandry.

1800 1. Soil. Science has already proved, in the most satisfactory manner the following circumstances regarding soil:

1801 "In order that it may be fertile it must contain all the mineral matters found on the surface of the plants destined to be cultivated upon it, in such a condition as to be available by the plants, and in sufficient quantity to enable the supply to be kept up by some economical mode of cultivation. The necessity of this condition depends upon the well-established fact, that plants cannot make for themselves any of the elementary substances which they contain, but are only capable of changing the form in which these are combined with one another. Thus, the organic portion of plants, or that which is destructible by fire, is composed of four elementary substances, namely carbon or charcoal, and three gases named oxygen, hydrogen, and azote. Now plants cannot produce any of these four substances under any circumstances whatever, but if they are supplied with them, in almost any state of combination, they can, by their vital processes convert them into starch, gum, woody fibre, or whatever else they may require. The same is the case with the constituents of their sapes. They must be supplied with the requisite elements in some state of combination, and then they will be able to produce for themselves the particular compound which they require. Dr. Madden admits that a considerable increase of knowledge is required among farmers before this part of agricultural science can be brought to perfection, though he believes that much of the future progress of agriculture depends upon increased knowledge in this department of agricultural chemistry.

1802 "2. Soil must consist of a due admixture of insupportable matter and larger sized particles, so that it may be porous and easily permeable by air and moisture, while at the same time, there is a sufficient supply of matter in a state capable of undergoing chemical changes. All the useful organic matter of soil is in a combination with the insupportable earths which it contains, though the larger particles are necessary for the stimulation of air and water. Till these larger particles are reduced to powder they exert no direct influence whatever upon the vegetation of the soil of which they form a part.

1803 "3. Soil must contain a sufficient supply of organic matter mingled with it in a state capable of decomposition by the action of air and water. In general the quantity of vegetable and animal matter in a soil is a direct index of its fertility.

1804 "4. Soil, to be fit for profitable cultivation, must be free from any mineral substance which is destructive of fertility. "This is a case in which no farmer will doubt the utility of chemical knowledge; thus, if the injurious matter be an acid or a soluble salt of iron, it may be neutralized by lime, or if it should be some compound of magnesia, it may be rendered innocuous by exposure to the atmosphere.

1805 "5. Soil must be capable of being reduced to a sufficiently fine state without an undue amount of labour, in order that its culture may be profitable.

1806 "6. Soil for a good farm must either be naturally capable of being off any superabundance of water, or it must be capable of being made to do so artificially by draining. The advantages of draining a soil naturally moist can hardly be over rated. It not only admits air to the roots of plants, but admits the temperature of the atmosphere, so that a drained soil will always be found to produce an earlier vegetation than the same soil undrained."

1807 "7. Soil, to be useful in the cultivator must possess a structure which will allow the decomposition of organic matter mingled with it to proceed at a regular rate, being neither so fast as to waste the manure, nor so slow as to keep it too long from it. Hence gravel, coarse sand, or strong clays, are to be improved by the addition of soils of an opposite texture, by the use of suitable manures, and by appropriate mechanical treatment, such as exposing strong clays to the frosts of winter, or the intense heat of summer sun-drying loose gravels or sands, &c."

1808 "8. The situation of soil must be such as to admit of all the operations of husbandry being per-

*formed in a proper manner without occupying too much time and the climate must permit of the plants surviving the frost.*

807.—8. In order that soil may be advantageously subjected to continuous cropping, the farmer must keep up its essential qualities by ploughing, harrowing, and any other operations necessary to preserve it.

807.—10. Good intention for continual cultivation must have its supply of organic matter, and must also of the mineral ingredients, consumed by returning to it, from time to time, in the shape of manure, what has been removed from it in the form of crops.

807.—11. The condition, as well as the composition, of the manure must be attended to, because soil must have its activity preserved by adding to it, at certain periods, substances in a state of fermentation.

Numerous facts tend to prove that the success of many crops depends upon the existence of fermenting matter in the soil, and that however rich it may be in other respects, these crops can only be advantageously cultivated after a fresh addition of manure. This is particularly the case with the turnip. Without dung the richest soil will bear but an indifferent crop. While with manure, very poor soil, if it be not too wet, will at all times give a good return. Science has not as yet been able to account for this satisfactorily although many of her votaries are willing to acknowledge its truth, and it is obvious that an acquaintance with the fact must be of the greatest value in assisting the farmer in his arrangements, for he will of course apply dung when he intends to raise a crop requiring the existence of fermenting matter and thus insure its success, while he does no injury to the following crops, whose growth is, to a certain extent, less dependent on the condition of the soil.

807.—12. To correct any natural faults which the soil may possess it must be subjected to various processes which have been proved by experience to cure the faults in question. The chief of these are draining, liming, and burning.

8078. Draining. The importance of draining, and especially of furrow draining is now very generally understood, and the fact is so widely extended that it is in some danger of causing the advantage of deep draining to be overlooked. "A soil which is naturally capable of easily getting quit of surface water may be rendered quite marshy by the existence of a spring. Now to furrow drain a field of this kind would, in many cases, be absurd, for in all probability the spring would be missed and after all the expense of laying the drains, the soil would remain almost as wet as at the first. The proper treatment, in such a case, is to search for the rise of the spring in the highest part of the field, and having found it one good drain will frequently have the effect of drying the whole field. Again, when the wetness arises from both causes conjointly viz spring and surface-water it is obvious that however free an exit be given to the spring, the soil cannot be made dry without having recourse to furrow-draining to a greater or less extent, according to the stiffness or porosity of the soil and subsoil.

8074. Liming. Lime has three distinct great effects in addition to several minor ones. 1st It greatly hastens the decomposition of the organic matter in the soil and in doing so renders it much more valuable to the crops. 2d. It alters the texture of the soil to a certain extent, proportioned to the quantity applied. 3d. It adds, of course, calcareous matter to the soil. From these considerations it follows that lime is applicable to all cases where there is an accumulation of undecomposed vegetable matter as in poor old pasture, heath, peat, moorland, and the like. Lime is not required in soils which are poor for want of organic matter nor in such as abound in chalk. Lime does not add directly to the fertility of the soil but only increases it, by calling into activity organic matter. Lime exhausts the soil by bringing the organic matter which it contains into action, and hence many lands will yield for a year or two after liming heavier crops than they did before, but afterwards their productive power fall as much below the natural standard as they had been artificially raised above it by liming.

8074. Burning. The immediate effects of this process are fourfold. 1st. It destroys a large quantity of organic matter. 2d. It alters entirely the texture of the portion to which the heat is directly applied. 3d. It reduces to a caustic state the alkaline and alkaline earths contained in the burnt portion. 4th. By means of these alkalies it acts upon the remaining organic matter of the soil exactly as lime does. To arrive at a just conclusion as to the true economical merits of this process we must bear all these four facts in mind. 1st. As it destroys a large quantity of organic matter it of course exhausts the soil to the extent of the quantity destroyed. This is therefore in one respect, a disadvantage. 2d. As it completely alters the texture of the portion burnt viz by giving to it the play the feeling and texture of sand we must consider how far this would be advantageous to the soil. 3d and 4th. As it produces alkali which acts upon the remaining organic matter of the soil and thus further detracts from its supply of organic matter it becomes of importance to decide whether the soil will bear the deterioration without a real loss of value.

8076.—11. THE EFFECTS OF VEGETATION UPON SOIL. Science explains more or less satisfactorily the causes of the following facts.

8077.—1. Unimproved soil, however rich, becomes gradually less and less fertile until it has attained the condition either of moor or marsh.

8078.—3. Unimproved soil retains its luxuriance for the greatest length of time when covered with forest trees and other large vegetables.

8079.—5. Land not disturbed by the plough produces successive crops of different kinds or in other words a sort of natural rotation is to a certain extent, maintained.

8080.—4. On cultivated land when any species of plant disappears its place is supplied by one of less value as an article of food, and thus the richest pasture comes in time to produce only the coarsest and most worthless species of grass.

8081.—5. Although the natural produce of uncultivated soil thus uniformly decreases in value the soil itself becomes progressively richer so that when brought under the plough, it will yield much larger returns than could be expected from its spontaneous produce.

8082.—6. Soil continually ploughed yields its nourishment in much greater abundance and with greater ease to plants growing upon its surface.

8083.—7. The fertility with which the productive powers of well cultivated land are diminished depends on its organic matter being more easily converted into compounds soluble in air and water.

8084.—8. The decrease of fertility in carefully cultivated soil depends in addition to the above circumstances upon a diminution in the proportion of its valuable matter.

8085.—9. Cultivated land, when properly taken care of becomes gradually richer and richer notwithstanding the increased quantity of produce annually removed from it.

8086.—10. If the same plant be cultivated for several years successively upon the same spot the soil much more rapidly decreases in fertility than when a variety is kept up.

8087.—11. Some of the most valuable mineral constituents of soil decrease in greater rapidity in proportion to the greater care bestowed upon its cultivation, altogether independent of the portions removed by the crops. The more you pulverize a soil, the more alkali will be annually removed by the run water.

8088.—111. THE ART OF CULTIVATING, or the means necessary for keeping up the fertility of the soil, require—

8089.—1. Manure added in proportion to the weight of the crops removed.

8090.—2. A judicious rotation of crops.

8091.—3. Ploughing at least in some soils.

8092.—4. Mowing by laying down in pastures.

8093.—1. Manure must be added in proportion to the weight of crops removed. "It is believed that careful examination will prove that there exists between the crop and the active organic matter in the soil, a proportion so constant and definite, that to keep up the fertility of the soil, we must keep up this

proportion and if we do this by manure, of course it follows that there is a certain fixed proportion between the manure and the crop. Calculation will show us that although at first sight the gross weight of the crops of a rotation is considerably above that of the manure applied, still, in reality the amount of the various elementary matters is much nearer an equality in fact, are generally most abundant in the manure. Let us, for example, suppose the following case — an imperial acre of turnip soil receives 31 tons of farm-yard dung, and yields, 1st, 20 tons of turnips 2d 42 bushels (of 48 lbs each) of barley 3d 2000 lbs of straw 4th 24,500 stones of hay 5th 48 bushels (of 48 lbs each) of oats, with 2000 lbs of straw. Now the gross weight of these crops would be 80,542 lbs whereas the manure would weigh only 66,000 lbs and consequently the soil has yielded 24,542 lbs more in four years than it received in the form of manure, or at the rate of 6086½ lbs more annually. If, however, we compare separately the relative quantities of carbon, azote, and saline matter contained in the crops and manure, we shall obtain the following results:

	lbs.		lbs.
Carbon in the crops	8168 04	In the manure	12,734 4
Azote in the crops	248 61	In the manure	166
Saline matter in the crops	1191 24	In the manure	8,104
	9,623 90		20,118 4

So that, in fact, there is a considerable excess in the manure of all the elementary ingredients of the crops if we except the elements of water, viz oxygen and hydrogen. We trust that this calculation will be sufficient to satisfy all, that there exists a certain proportion between the weight of the elements of the crop and that of the constituents of the manure.

8004. *A rotation of crops is repugnant to soil weary because it tends greatly to lessen the expense of cultivation, but because the more crops a field contains the less frequently can it be cultivated, even the same spot is unprofitably succeeded.* The precise chemical principles upon which a rotation depends are somewhat obscure.

8005. *A naked summer fallow only becomes necessary when soil cannot be cleared and brought to a sufficiently fine state between harvest and the following seed time without interfering with other operations.*

8006. *V The Economy of Husbandry or the particular regarding each individual crop which are necessary to be known in order to its successful cultivation.* The following general facts in vegetable physiology will assist us in understanding this part of the subject.

8007. *1. All plants in a highly artificial state require a larger supply of nourishment during the first period of their growth than is supplied by the seed alone and hence the necessity of a rich soil, or of a supply of nutritious manure.*

8008. *2. Plants which have more than one method of propagating themselves should be limited to the method which is most suitable.* The potato should not be allowed to produce seed, because it is most conveniently propagated by the tuber.

8009. *3. Plants lay up a store of nourishment for the next year either in the wood or roots as in trees and perennials or in the seeds as in annuals.*

8100. *4. The starch of plants is always contained in cells formed of a substance containing azote and consequently there exists a fixed proportion between the quantity of azote composing the cells and the amount of starch contained in them hence it follows that to increase the quantity of starch in a plant you must increase its supply of azote although starch itself contains no trace of this element.*

8101. *5. In all parts of a plant there is an exact proportion between the various elements entering into its composition, so that an addition to one of them is necessarily followed by a relative addition to them all.* If for example a plant possesses one part containing 3 grs. of azote, combined with 18 grs. of other elements and another portion containing 3 grs. of azote combined with 48 grs. of other elements if we by any means, prevent the development of the more highly azotised portion viz the 3 to 18, we shall produce a proportional increase in the other so that by preventing the formation of 30 grs. of the highly azotised portion we obtain 50 grs. of that which contains proportionally less azote.

These facts will assist us in the following explanations regarding individual crops.

8102. *The turnip.* The funiform, or globular part of the root of the turnip contains the supply of nourishment required for the development of the flower and seed in the following year. The turnip has a large system of leaves contains much water, is not highly azotised the seed possesses a very small supply of nourishment the whole success of the crop depends, within certain bounds, upon the rapid development of the large absorbent leafy surface. Hence the culture of the turnip must be conducted as follows — the soil must be sandy, first because it is a law that plants make preparations for retaining in their own texture most water when the soil around them is capable of retaining less; second because its development must be rapid, and hence the decomposition of manure must be rapid likewise. There must be a good supply of very active manure, so that the seed may be provided with abundance of food in the first period of its growth and thus have its leaves developed as rapidly as possible (within certain limits of course). As the plant is not highly azotised it can draw the greater portion of its nourishment from the air provided the absorbent surfaces of the leaves be sufficiently large hence it is more necessary to attend to the quality than the quantity of the manure for this crop. A small quantity in a very active state, will prove much more valuable here than a large quantity which is too fresh. At the size of the bulb is regulated by the size of the surface of its leaves, this crop must not be too crowded, but plenty of room should be left to permit of the full development of the leaves.

8103. *The potato.* The potato differs essentially from the turnip, in that the portion used is a perfectly developed part, that is to say a part which is perfect in itself. For instance the bulb of the turnip is merely a deposit of nourishment for the use of the plant during the ensuing spring and if removed from the soil cannot be made to produce a new individual whereas the tuber of the potato is as much a perfect individual as any seed, for it contains within itself all that is requisite for the propagation of the species. On this account, therefore the potato may be considered as perfectly developed when the tuber is ripe whereas the turnip has merely advanced a certain way towards perfection, which cannot be said to occur until the seed is formed. Now the importance of this distinction will be seen, when we remember that all plants deteriorate the soil most during the latter periods of their growth, and hence it follows that, *seriatim* *pariter* the potato is a more exhausting crop than the turnip. The potato like the turnip, has a large system of leaves, and contains much water. It is more azotised than the turnip, but the portion containing the greatest quantity of azote is not developed until during the later periods of the growth of the plant. It possesses two ways of propagating its species, viz by seeds and tubers and whatever prevents the development of the one, increases proportionally that of the other, this proportion being regulated by the quantity of azote. The success of the potato depends greatly upon a due balance between the quantity of nutriment afforded respectively by the soil and the air because the tuber consists of a large deposition of starch in cells composed of an azotised matter. Now as the soil provides the material for the cells, and the carbonic acid of the starch is deriv'd chiefly from the air it follows that if one or either of these supplies be in excess a due proportion will not exist between the two ingredients of the tuber. Thus, if the soil be very rich in azotised matter so many cells are produced that the leaves cannot eliminate starch sufficient to fill them on which account, the potato is of that peculiar consistence termed waxy. If, again, the soil is deficient in azote, only a few cells are formed, and these are completely filled with starch and the potato consequently becomes mealy. With regard to the order of development of these parts, the cells are first produced, and become filled with starch subsequent to the development of these parts, the leaves are first produced, and become filled with starch subsequently and as is formed by the leaves any thing which injures them such as frost, or checks the

production of starch, and the potato requires either waxy or waxy or waxy, salt and waxy. Now, a series of these facts would lead to the following suggestions regarding the culture of this plant:—

8194. 1st. "There must be an abundant supply of manure, because, not only must the tubers be quickly developed, but the soil must be in a condition to yield roots abundantly, even during the later period of the growth of the plant; hence, small quantities of active manure will not succeed nearly so well with this plant as with the turnip."

8195. 2d. "The manure need not be so well prepared, as the greatest supply of manure is not selected until some time after the plant has risen above ground, but it must not be too fresh, for fear of retarding the development of the leaves, nor too hot, for fear of acting injuriously on the seed or tubers."

8196. 3d. "We must not give this crop too much rich manure, for fear of making a greater demand upon the atmosphere than it is capable of answering."

8197. 4th. "The plants should be placed far apart, so as to permit of the free expansion of the leaves."

8198. 5th. "As the potato has a spreading root, and the tubers are nearly all developed upon the under surface of the fibres which run most horizontally, it is very injudicious to earth up the plants, as this of necessity renders the roots more perpendicular. Experiment has proved that this practice occasions considerable loss."

8199. 6th. "To obtain the largest number of tubers, the flowers should be plucked off to prevent the formation of seed, while every thing should be done to protect the leaves from injury."

8200. 7th. "The soil for the potato should be loose, although this plant will grow in a much greater variety of soil than the turnip. This also depends upon the tubers being a completely developed portion destined for the production of a separate individual, whereas the bulb of the turnip is for the purpose of supplying the plant during the most important period of its growth, viz. during the development of the seed with abundance of moisture and nourishment, when growing in a soil which cannot naturally retain these, and therefore, if we attempt to grow the turnip upon stiff soil, it either does not flourish at all, or else the bulb is very imperfectly developed, for in this case the soil can supply all that is required, without the assistance of this artificial reservoir."

8201. 8th. "Wheat, oats, and barley. All of the cereals agree in so many respects that it will be advantageous to consider them together."

8202. 1st. "As they are cultivated for their seed, they are perfectly developed before harvest, and therefore, exhaust the soil to a much greater extent than green crops."

8203. 2d. "As their system of leaves is very much less than that of the plants before considered, they are much more dependent upon the soil even for those elements which larger leaved plants obtain from the air."

8204. 3d. "As the seed is, in all instances, the most highly seeded portion and as it is the last part developed, it follows, that these plants require more a general richness of the soil than a supply of newly added manure. On this account, it is with propriety, therefore, that they are seldom made to follow a close after the application of manure, but are either preceded by a green crop, or are sown after summer fallow."

"These crops differ among themselves chiefly as regards soil and climate, wheat requiring clay, barley a lighter soil, and oats succeeding pretty equally on all good soils of whatever texture they may be. The same is the case concerning climate, and the richness of the soil.—wheat requires the best climate and the richest soil, then barley, and then oats. It is not easy to explain this satisfactorily, for although we can produce many circumstances which appear to explain the differences in question, more careful examination will prove that they can merely be considered in the light of probabilities, and by no means as certainly ascertained facts. For example, if we examine the ashes of these three plants, we find that their quantities amount proportionally to three two and one wheat containing the most and oats the least, and if we examine still further we shall find that clayey soil is more capable of yielding the ingredients of these ashes than land of a lighter texture. This renders it probable that one of the causes of wheat requiring clay depends upon the necessity of a larger supply of these earthy particles, but accurate calculation also proves that many plants which grow best on sand remove from it a greater quantity of these very substances than would be required to supply the heaviest crops of wheat. It cannot, therefore, be considered as proved that the cause of wheat preferring clayey soil, depends upon the greater quantity of earthy matter required for its perfect development, although we may venture to advance as a probability that it depends upon an increased facility of obtaining this supply. Again, these three crops require a considerable supply of manure during the later periods of their growth, the proportion being, wheat 3:12, barley 1:7, oats 1:10, so that here again, since we know that decomposition proceeds more slowly in clay and the action of the manure is hence not so quickly given off, we might argue that clay would be better suited for wheat. Chemical analysis, however, proves in this case also, that some crops peculiarly suited to sandy soils contain a much larger absolute quantity of manure although it must be admitted that the relative proportion is much less. Our conclusion here, also, must therefore be, that the cause of wheat thriving best upon clay depends probably upon its receiving manure in a greater degree of concentration."

8205. 4th. *Beans, peas, and other leguminous plants.* "Very little can be said regarding these in the present state of our knowledge, as but little particular attention has hitherto been paid to them by the scientific inquirer, and there are so many peculiarities exhibited by them that it would be very imprudent to risk an opinion upon so meagre a collection of facts. Beyond all doubt these are the most hazardous crops we cultivate, as they are so very much influenced by the weather. Clover for example, is a plant the success of which we can scarcely in any instance predict, as, no matter what the state of the soil may be, a few days of unfavourable weather may destroy it once all prospect of success. We may however notice one fact in this place, although we shall not attempt its explanation, viz. that the nitrates of potash and soda, two very favourite manures, appear to exert an almost magic influence over clover in rendering it much more certain and luxuriant."

These observations complete Dr. Mendley's review of the facts in agriculture, which are already explained by science; he regards them as showing that considerable advances have of late been made, and he hopes soon to see the farmer and the philosopher reading forward hand in hand in the field of agricultural improvement. He subjoins the following tables:—

1. Table showing the relative nutritive Powers of various Articles of Food, deduced from the Quantity of Azote which they contain. Arranged from M. Boussingault's Tables.

Name.	Percent kinds of Matter.		
	Azotum per cent of Solid Matter.	Azotum per cent of Azote.	Value compared with Hay at 100.
Hay, from red clover in flower	89.4	1.75	100
Yield hay	85.0	1.44	74
Luzerne hay	89.4	1.85	75
Common hay	85.0	1.04	100
Green clover	—	50	200

\* That is to say, that 89 lbs. of red clover hay contain as much nourishment as 100 lbs. of common hay, and as 512 lbs. of turnips.

Potatoes	77	80	80	
Green leaved	104	104	104	
Carrot	50	50	50	
Wheat straw	60	60	60	
Barley straw	70	70	70	
Oat straw	70	70	70	
Rye straw	70	70	70	
Turnips	80	80	80	
Beets	80	80	80	
Vegetables	80	80	80	
Kidney beans	80	80	80	
Lentils	80	80	80	
Yellow peas	80	80	80	
Wheat flour	80	80	80	
Wheat grain	80	80	80	
Rye	80	80	80	
Oats	80	80	80	
Barley flour	80	80	80	
Barley grain	80	80	80	

† Leguminous plants alone will not prove so nutritious as the cereals, because they do not contain a sufficiency of phosphates which are required for the production of bone; they are therefore most useful when conjoined to some of the following grains

II Table showing the Composition of the Ashes of our most frequently cultivated Crops. From *Chemists and other Authorities*

Name	Ashes in 1000 Parts.	Composition of 100 parts of the Ashes.				
		Soluble Salts.	Phosphates.	Berthy Compounds.	Silica.	Metals Oxides.
Wheat grain	12	47-16	44-5	1	7	75
Wheat straw	43	32-6	6-2		51-6	1
Oat grain	31	1	24		57	25
Barley grain	18	30-5	35-5		30-5	25
Vegetables	23	60-25	27-22			0-5
Turnips	8-5					
Potatoes	6-2					

III Table showing the Quantity of Alkali associated with the various Minerals entering into the Constitution of Soil. From *Liebig*

Name of Mineral.	Per Cent of Alkali.	Name of Alkali.
Felspar	17-75	Potash.
Albite	11-43	Soda.
Micro	3 to 5	Soda.
Zeolite	13 to 16	Soda and Potash.
Basalt	5-75 to 10	Soda and Potash.
Clayalite	2-75 to 3-51	Potash.
Clintonsite	14	Potash.
Lepan	1-5 to 4	Potash.

Analysis has proved the existence of more or less potash in all clays, as also in marls. From this table it would appear that by far the best soil would be that originating from the disintegration of felspar and we think that observation will often prove this to be the case

## BOOK II

### THE ANIMAL KINGDOM WITH REFERENCE TO AGRICULTURE. (p. 281)

8116. — 1828. *Animals* according to Liebig, are subject to the action of two powers which are constantly at work: vitality, which is the cause of life, and chemical affinity, which is the cause of death. The object of vitality is to sustain and increase the mass of the body in which it resides; the object of the chemical force is to destroy and waste that body. Vitality resides in every part of the fortress which it has to defend; the chemical force are consumed in the atmosphere which everywhere surrounds it. In fact, the chemical power is the gas oxygen, one of the principal constituents of common air; and its affinity for the elements of organic matter is so great, that it constantly endeavours to destroy it. The whole life of an animal consists in a conflict of these rival powers: in the endeavour of vitality to sustain and increase; in that of chemical affinity to waste and destroy. In health, vitality prevails; in disease, and in death, the destructive efforts of the chemical power. Disease, on the other hand, is a temporary conquest of the chemical over the vital forces; while death is the victory of the former, and annihilation of the latter. (See *Journal of Science*, vol. I, p. 281.)

8117. — 1828. The food of all animals and particularly of those employed in agriculture, Liebig has shown to consist of two elementary substances: gluten or albumen, composed of carbon, hydrogen, nitrogen, and oxygen which constitutes the nutriment of the body; and starch, sugar, gum, and other substances containing carbon, hydrogen, and oxygen, but from which the element nitrogen is absent. It is only the substances containing nitrogen or which in other words are unoxidized, which produce flesh, while the other elements are for the production of heat by the combustion of carbon in consequence of its union with oxygen. The heat generated in this combustion is the body of an animal, is exactly equivalent to that produced by burning the same amount of carbon in a fire or a candle. As the heat

of an animal body is the same in all regions, it follows that more carbonaceous food is required to keep up the animal heat in a cold region than in a warm one, and hence the great importance of protecting animals from a greater degree of cold than is natural to them in every stage of their growth, and for obvious reasons it is equally important to protect them from extreme heat. This subject has been beautifully illustrated by Liebig, who says, "were we to go naked like certain savage tribes, or if in hunting and fishing we were exposed to the same degree of cold as the Scythians, we should be able with ease to consume 10 lbs. of flesh, and perhaps a dozen of tallow candles into the bargain as warmly clad travellers have related with astonishment of these people. We should then also be able to take the same quantity of brandy or train oil without bad effects, because the carbon and hydrogen of these substances would only suffice to keep up the equilibrium between the temperature of the external air and that of our bodies." (*Chemistry as applied to Physiology* &c.) The only use of clothes, says Dr Playfair is to economise food by retaining heat. (*Lectures on the Applications of Physiology to the Rearing and Feeding of Cattle in Jours. R. A. E.* vol. iv p 231) The animal body is a furnace which must be kept up to a certain heat in all climates. This furnace must, therefore, be supplied with more or less fuel according to the temperature of the external air. If then, in winter we wish to retain the vital functions of our cattle in a proper degree of activity we must keep up the heat of their bodies. This we may do in two ways. We may either add more fuel (food) to the furnace or we may protect their bodies from the cold. Warmth is an equivalent for food, and as a proof Dr Playfair cites the following experiment, which was made by the Earl of Dundee at Whitehall farm. One hundred sheep were folded by tens in pens each of which was 20 ft. in length by 10 ft. in breadth, and possessed a covered shed attached to it of 12 ft. in length by 10 ft. in breadth. They were kept in these from the 10th of October to the 10th of March. Each sheep consumed on an average 50 lbs. of Sweden daily. Another hundred were folded in pens of a similar size, but without sheds attached. They were kept during the same time, and their daily consumption of Sweden amounted to 50 lbs. each. Here the circumstances were precisely similar with respect to exposure, the only difference being that the first hundred sheep had sheds into which they might retire and thus be partially protected from the cold. This partial protection was equivalent to a certain amount of food, and consequently we find that the sheep enjoying this protection consumed one-fifth less food than those sheep which were left entirely exposed to the cold in the last case the consumption of the additional food arose wholly from the necessity of adding more fuel (food) to the furnace of the body in order to keep up its normal temperature. This was proved from the circumstance that those sheep which enjoyed the protection had increased 3 lbs. each more than those left unprotected, although the latter had consumed one-fifth more food. (*Jours. R. A. E.* p. 323) The honey stored up by bees is for the purpose of serving as fuel to keep up the heat of their bodies during the winter. Now it has been found that when two hives of bees are placed in one hive during winter they actually consume less honey than each hive would have done separately.

§117. *The summative power of the grossness is enormous, and the quantity of food which they consume is proportional.* In summer when the temperature of the air approaches more nearly to that of the body the heat generated by the combustion of this food is more than is sufficient to retain the normal temperature of the system. Hence it is that we find oxen so much inconvenienced by hot weather as that we observe them standing in streams of running water or exposing themselves, with evident satisfaction to a shower of rain. The cold water serves to carry off the redundant heat, and consequently matter from the body for heat is produced by the combustion of matter. This practice therefore, although agreeable to the cattle, can scarcely be a profitable one for the grazier and hence as before intimated, the advantage of a shed in summer to exclude the heat, as in winter to retain it. "The air in summer being so much expended by heat, much less air is taken into the system in an equal number of respirations than in winter, consequently less oxygen is consumed. But oxygen is the principal acting chemical force. It is, therefore, the cause of waste. The case of cattle now feeding is the very reverse of what it is in winter. In cold weather the vital force (cause of supply) is reduced in activity whilst that of the chemical force is augmented; but in summer the vital functions are elevated and the chemical powers depressed. Vitality having now a diminished force in antagonism to its action exerts all its powers in increasing the mass of the organs in which it resides; it therefore can exert into blood all essential parts of the food taken by the animal, except those which supply the small amount of waste. All the excess of blood is converted into flesh (i.e. muscular tissue and cellular tissue). The animal now becomes fleshy and plump. The other constituents of the food, such as starch, sugar and gum, are converted into fat, and deposited as adipose tissue. The cause of the deposition of fat is this: that sufficient oxygen does not enter the system to consume the food, or to convert it into carbonic acid and water; it is, therefore, only partially consumed, or in other words, converted into fat (Liebig). Fat is not a part of the organism; it is a chemical compound arising from an unusual state. The fattening of cattle is similar to the growing of corn plants or to agriculture generally. The object of agriculture is to produce an abnormal increase of some particular constituent of a plant, such as of gluten in the wheat. This we do by chemical means, by manure. The fattening of cattle is similar. Our object is to produce an unusual increase of some particular parts of the body and to do this we must put the cattle in an unusual state. (*Jours. R. A. E.* vol. iv p 324.)

§118. *Exercise.* The most favourable conditions to the development of fallow are food deficient of nitrogen, warmth, want of exercise, and in some cases darkness. Motion diminishes the tendency of an animal to fatten, by increasing the number of its respirations, and therefore by giving to the system an increased supply of oxygen gas, which consumes the fallow. Hence our practice of stall-feeding cattle. Liebig asserts, "that every motion, every manifestation of force, is the result of a transformation of the structure or of its substance; that every conception, every mental affection, is followed by changes in the chemical nature of the secreted fluids; that every thought, every sensation is accompanied by a change in the composition of the substance of the brain. There is a constant conflict in the body between the two antagonist powers, vitality and chemical affinity. In the state of health, vitality retains the ascendancy, and subdues the chemical power; but this subduence is the result of much effort on the part of vitality for the strength of the rival forces is nearly equal. The moment, therefore, that vitality leaves undivided a single point in the fortress of the body, that moment the chemical forces begin the work of demolition on the unprotected part. Thus, if vitality be called upon by the superior power, volition to execute some purpose of its will, — to move the arm for example — the vitality residing in the muscles of the arm obeys this command, and executes the desired movement. Before the production of motion, all its powers were exerted in preventing the encroachment of the chemical forces (i.e. of the oxygen of the air). But when it is employed in effecting a vital movement such as that of the arm, it is no longer in a position to resist the attack of its antagonist power. This, therefore, immediately acts upon the muscles, which obey the will, destroys part of their substance, and occasions its separation from the tissues. Fowling-keepers condemn their poultry when it is necessary to fatten them quickly. The cruel practice of muzzling the feet of geese to the ground during fattening is owing to the anxiety of aversion feeders to prevent the expenditure of a particle of the food by the motion of the animal. The greatest part of the food consumed by an animal thus deprived of the means of motion goes to the production of fat. When pigs are put up to be fattened, they are removed from the yard, in which exercise is permitted, and placed in a narrow sty, with little room to move. A small amount of the food being now expended in the production of motion, the pig rapidly increases in size. Sheep fed in sheds consume from one-fifth to one-half less food, and increase one-third more in weight, than those fed in the open field. The cause of these results is two-fold: — first, the sheep in the sheds are subjected to less motion, and therefore exhaust less food in its production than those in the field; and, secondly, the sheep are kept warm in the sheds, and therefore expend less food for the support of animal heat than those

exposed to a cold atmosphere in the open fields. It is well known that the more bodily labour to which a man is subjected the more food must he receive to supply the wastes wasted in that labour. In the late distress in Lancashire, the poor sufferers, who often were unable to obtain sustenance for themselves and families discovered, through the force of necessity, both the theories which we have endeavored to expound, viz. that warmth is an equivalent for food, and that motion is always accompanied by a change of matter. We are informed by the daily press that whole families remained in bed for days together covered with as many clothes as their small stock could furnish. In this state the animal heat was artificially retained, and little matter being expended in motion, a small amount of food was sufficient to support the vital principle. (*Journ. R. A. S. E.* vol. iv. p. 387.)

§119 The importance of knowing how much water each kind of food contains, has been forcibly pointed out by Dr Playfair who has furnished the following table:

		Water.			Organic Matter.	Ashes.
		<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>		
100 lbs. of Peas	contains	16	804	24		
— Beans	—	14	834	25		
— Lentils	—	16	81	2		
— Oats	—	18	79	2		
— Oatmeal	—	9	89	2		
— Barley meal	—	15½	82½	2		
— Hay	—	16	764	7½		
— Wheat straw	—	18	79	2		
— Turnips	—	89	10	1		
— Swedish turnips	—	88	14	1		
— Mangold-wurzel	—	89	10	1		
— White carrot	—	87	13	1		
— Potatoes	—	73	27	1		
— Red-beet	—	69	10	1		
— Linseed-cake	—	17	764	7½		
— Bran	—	14	81	2		

Thus in giving a pig 100 lbs. of potatoes, we actually give it only 25 lbs., because 75 per cent. of this food consists of water.

§120 The comparative values of different kinds of food as far as the production of flesh or muscular fibre is concerned, is not less important because, as we have before seen, those kinds of food which do not contain nitrogen are only productive of fat or heat. The following table is given by Dr Playfair:

		Albumen.		Unassorted Matter.	
		<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>
100 lbs. of Flesh	contains	25	0		
— Blood	—	30	0		
— Beans	—	31	51½		
— Peas	—	30	51½		
— Lentils	—	33	48		
— Potatoes	—	3	25		
— Oats	—	11	36		
— Barley meal	—	14	62½		
— Hay	—	8	80½		
— Turnips	—	1	9		
— Carrot	—	2	10		
— Red-beet	—	1½	5½		

In a cold dry season ought to be furnished with food containing a considerable amount of unassorted ingredients in order to protect them from the effects of the cold. Potatoes are of great use in keeping up the heat of the body and in forming tallow but are in the highest degree unprofitable for forming flesh. "It will be seen by the table that 1560 lbs. of potatoes would be required to form the same quantity of flesh that 100 lbs. of beans would do; whilst little more than 200 lbs. would suffice to form the same quantity of tallow. Hence the great advantage of mixing food, so as to supply in smaller bulk those constituents of which one kind of food is deficient. Sheep fed on oil-cake increase in weight faster than on any other kind of food, but they feel quite soft, and when fat handle like a bag of oil. This is because they receive food which contains very little albumen to form flesh, so that tallow is the only product. But if with the oil cake they receive oats or barley they are firm to the touch, and possess plenty of good flesh, and the fat lies equally distributed amongst the muscular fibre. The reason here also is obvious, for both oats and barley contain much albumen (or chemically gluten). In an experiment made by Mr. Morton at Lord Dunsley's farm, twenty-eight pigs, put up in pairs of seven each, and fed on an average on 10½ lbs. of potatoes and 4 lbs. of barley meal each, gained 16 or 16½ lbs. weekly. In this quantity the pigs actually consumed nearly equal quantities of the two kinds of food, or exactly 80 lbs. of dry potatoes and 33 lbs. of dry barley meal weekly. The increase in weight being 16 lbs. for each pig, 57 lbs. of the food were lost in supporting respiration, and the necessary muscular movements, even without taking into calculation the water contained in the flesh of the animal, which amounts to 75 per cent. If these animals had been deprived of muscular movement by being placed in narrow warm cribs, it is reasonable to suppose that less food would have been lost, because less would have been consumed in the production of force and in sustaining the animal heat. The barley meal contains the constituents for furnishing firm flesh as well as for producing tallow or supporting respiration. The economy of using potatoes consisted in their supporting the respiration of the animals at less expense than barley. The 10½ lbs. of potatoes need 1½ the week for this purpose, and for the production of tallow contain 2½ lbs. of unassorted matter. In order to replace this, 33 lbs. of barley meal would be requisite. It does not invalidate the conclusion that 33 lbs. of barley meal would produce a greater return than 106 lbs. of potatoes, because the former contains much more albumen and less water than the latter." (*Journ. R. A. S. E.* vol. iv. p. 388.)

§121 The equivalent values of different kinds of food, if they could be correctly ascertained would be of great value to the farmer and the following table translated from the French by Mr. Rham, may be considered as near an approximation as can be obtained in the present state of our knowledge. On this table Dr. Playfair observes that an animal in a hot dry will require much less food than in a cold day; that equivalence of food may be correct as far as the same animal is concerned, but may be of little value as regards other animals because the size of the lungs of an animal occasions a great difference in the amount of food consumed.

	lbs.		lbs.
Of good hay	200	Boiled potatoes	175
Of second or third quality do.	100	White Miletan beet	200
Of Lotonensis hay	100	Mangel-wurzel	200
Clover hay, made when the blossom is	80	Turnips	200
completely developed	80	Carrots	200
Chenopium, before the blossom expands	80	Colza	200
Clover second crop	80	Swedish turnips	200
Lucerne hay	80	Ditto with the leaves on	200
Statens hay	80	Oats, rye	50
Barley	50	wheat	50
Swedish lucerne, dried	140	barley	50
Chenopium, after the seed	140	oats	50
Green clover	410	vetches	50
Vetches or tares, green	457	peas	45
Green Indian corn	175	beans	45
Green spermin	175	barley	50
Stems and leaves of Jerusalem artichoke	235	Indian corn	57
Oat-rabbings leaves	541	French beans, dried	32
Best-root leaves	600	chestnuts	47
Potato halm	300	acorns	68
Shelter wheat straw	574	horse-chests	30
Rye straw	443	sunflower seed	62
Oat straw	195	linseed cake	68
Peas halm	153	wheat bran	100
Vetch halm	153	rye bran	100
Beam halm	140	Wheat, peas, and oat chaff	167
Beck wheat straw	195	Rye and barley chaff	173
Dried stalks of Jerusalem artichoke	179	Dried lime-tree leaves	74
Dried stalks of Indian corn	400	oak leaves	85
Millet straw	280	Canada poplar leaves	67
Raw potatoes	301		

(Journ. N. A. S. E. vol. iv p. 80)

§123 The force on which food is given to cattle is far from being a matter of indifference. If the food be in a state in which it is either difficult to attain, or difficult to masticate when obtained much of it will be lost in the production of force necessary to adapt it for the organs of digestion. The cutting of hay and straw to chaff is unwittingly done with a view to prevent any unnecessary expenditure of force. Less mastication is requisite, and consequently less of the tissues of the body are expended in grinding down the food. The use of saliva, according to Liebig, is to form a receptacle for air or oxygen by which means it is raised with the food and carried to the stomach. The use of mastication, then, is not only to comminute the food, but also to mix it with air or saliva. We find that a larger size of chaff is given to those animals which chew the cud, than to those that do not. One great object of rumination is, to obtain a repeated supply of oxygen to the food. Hence, in our ordinary practice, we cut the hay chaff one inch in length for cows, half as much for sheep, and only quarter of an inch for horses. The two first being ruminating animals, require it longer than the horse, which is not one. When we consider that fresh grass is much more easily masticated than hay the economy of force exhibited in cutting the latter is well judged. Straw except when new is not a very nutritious food, for we find a great part of it unchanged in the faces of the animal fed upon it. Its principal use is to give a bulk to the food taken. Even in the case of turnips, a food of considerable bulk, straw is necessary, because they contain nearly 90 per cent. of water which becomes soon separated. Thus it is that cattle fed upon turnips voluntarily take 2 or 3 lbs. of straw daily or as much as will serve to give the necessary bulk to the food. Rumination is requisite in order to keep an ox in health. A little straw or hay is accordingly necessary to enable it to chew the cud. We know a case in which barley meal and boiled potatoes were given to cows without hay or straw. Constipation resulted, and the cattle nearly perished from the ignorance of the feeder. From these considerations, we are induced to consider that a greater return will be made by food partly but not too much reduced. The turnip-plot is known to save food, and this arises from the fact, that the sheep expend less force in eating sliced, than whole turnips, and to their being enabled to lie down more constantly. On similar grounds we are to ascribe the advantage of steaming food or reducing it to the state which the first three stomachs would otherwise have to do at a great expenditure of force, and consequently of food to produce it. (Journ. N. A. S. E. vol. iv p. 325)

§124 The use of salt in food. Respiration is carried on by means of the combustion of those constituents of the food which are destitute of nitrogen. But before this combustion is effected they are transformed by the liver into the fluid called bile. Bile is a compound of the alkali soda, with a viscid or highly carbonaceous substance derived from the food. The bile, after being formed, is absorbed by certain vessels of the intestines, and there meeting with oxygen, is consumed and converted into carbonic acid and water which are expelled by the lungs. The combustion does not take place in the lungs themselves, as is generally supposed, but in the intestines. Now, as bile is the medium through which respiration is supported, it is necessary that it should be properly and regularly formed. This can only be done by supplying the animal with a constant amount of soda. This we do in common salt. The soda of the milk aids in the formation of the bile whilst its muriatic acid assists the digestion of the food. A proper formation of the secretions is necessary to the health of an animal and a supply of salt is highly favourable to their production. But whilst it is admitted that a limited supply of salt is very useful to the health of the animal a large supply is highly prejudicial and prevents the formation of fat. An experiment was tried upon a goose, which was crammed with murex, and allowed to eat salt. The salt taken by the goose was less than that necessary to produce a purgative action and yet the goose did not fatten. This arose from the excreta of food being formed into bile, and not into fat. As much bile as was consumed as corresponded to the oxygen breathed, whilst the remainder passed out with the excrement and was detected therein. On this account, it is a bad practice to give feeding sheep as much salt as they will take in winter. (Journ. N. A. S. E. vol. iv p. 267)

§125 In the rearing and feeding of cattle, it is important to bear in mind that the process of nutrition differs in a young animal from that of an adult, and that no substitute has yet been found for the milk of the cow in rearing calves, though sugar, treacle, and flour of different kinds have been added to milk in order to make a sweet and nutritious food. The great point in the rearing of stock is to take care that the vital powers are always predominant over the chemicals. Attention to these considerations will really point out the kinds of food which are best adapted for a growing animal. Thus potatoes, without an admixture with other food, would be highly improper because they do not contain sufficient albumen to supply the materials necessary for the growing frame. But it would be quite proper to mix potatoes with other food rich in albumen, for its starch might support the respiration and heat of the animal with more economy than another food containing much albumen but a less abundant supply of substance fitted for respiration. It is a mistake, into which many breeders fall, to deprive the young animal of exercise by confining it exclusively in the stall. Such a procedure is perfectly correct with a suckling calf but not with one which is rearing. The muscular apparatus of a young animal requires a certain degree of exercise, without which it cannot increase. Unless the vitality resulting in the various organs be called into action,

it becomes satisfied, and as vitality is the agent of increase in the body, any diminution of its power is highly prejudicial to growth. The amount of exercise must of course vary with the age of the animal." (*Journal A. S. S. B.*, vol. iv p. 341.)

6120. That exercise is equivalent to food in feeding animals, has been abundantly shown. Mr. Morison found that sheep kept in summer were fatter in the cold wet days of winter, than when the weather is dry and warm, and in winter weather than in mild dry weather. The difference being equal in one fourth of the whole of their fat. Pigs fatten faster in summer with the same food, than they do in winter. The protection of a shed has saved one fourth of the whole food; and Mr. Chittenden has shown (*Journal A. S. S. B.* vol. i p. 307) that whose motion was at the same time prevented, the saving amounted to as much as one fourth of the whole of the body. While the health being better in the latter case, and only a small amount of exercise permitted the increased energy of the vital powers may more than compensate for the loss experienced by the motion of the animal. The flesh of the cattle in the yards must also be firmer and more suited for the butcher, while the cattle tied to stakes will, in all probability be possessed of more tallow. (*Journal A. S. S. B.* vol. iv p. 345.)

6121. The feeding of cattle for dairy purposes, has occupied Liebig and Dr. Playfair, but it would require more space than we can afford to explain their views, and we must, therefore, refer to the original sources. The same remark will apply to Dr. Playfair's remarks on the diseases of cattle and to the recognized signs of fattening and of early maturity. The theory of fattening adopted by Liebig and Dr. Playfair is or appears to be in total opposition to all opinions at present entertained. According to them, the peculiar aptitude of any animal, or of a breed to fatten, must arise from a peculiar smallness and fineness of texture of the lungs. Although Liebig has not announced in his work the opinion that smallness of lungs is an indication of a tendency to become fat, still he concedes that it is so. On consulting some eminent physiologists in our own country I find that they also entertain the same view. (This asserts quite the contrary and agriculturists have generally acceded to his opinion. He says, an animal with large lungs is capable of converting a given quantity of food into more nourishment, and therefore has a greater aptitude to fatten. Mr. Youatt holds a similar doctrine, and both he and Mr. Clive uphold their opinion by reference to the capacity of the chest. On the roundness and capacity of the chest, says Mr. Youatt, depend the size and the power of the important organs which it contains the heart and the lungs, and in proportion to their size is the power of converting food into nourishment. (*Journal A. S. S. B.* vol. iv p. 347.)

Those who would wish to pursue this subject will have recourse to the original, the interest of which would be in a great measure destroyed by abridgment, and it is too long to quote. We can however recommend these two lectures, at next to the volumes of Liebig the most interesting and instructive discourses with reference to agriculture which have appeared in our time.

6122. The nutriment afforded to animals by seeds and roots depends on the rupture of the ultimate globules which constitute their meal or flour. These globules vary in different roots, tubers, and seeds. Those of potato starch are usually from the fifteen to the twentieth part of an inch, and so on. From experiments made on these globules by M. Raspail, the author of *Chimie Organique* and M. Biot, of the French Academy of Sciences, celebrated for his researches in the polarization of light, the following conclusions have been drawn:

1. "That the globules constituting meal, flour and starch, whether contained in grain or roots are incapable of affording any nourishment as animal food till they are broken."
2. "That no mechanical method of breaking or grinding is more than partially efficient."
3. "That the most efficient methods of breaking the globules is by heat by fermentation or by the chemical agency of acids or alkalis."
4. "That the dextrine which is the kernel, as it were, of each globule, is alone soluble, and therefore alone nutritive."
5. "That the shells of the globules, when reduced to fragments by mechanical or heat, are insoluble and therefore not nutritive."
6. "That though the fragments of these shells are not nutritive they are indispensable to digestion either from their dissolving the stomach and bowels or from some other cause not understood, it having been proved by experiment that concentrated nourishment, such as cane-sugar, essence of beef or osmazone, cannot long sustain life without some mixture of coarser and less nutritive food."
7. "That the economical preparation of all food containing globules of fecula consists in perfectly breaking the shells and rendering the dextrine contained in them soluble and digestible, while the fragments of the shells are at the same time rendered more bulky so as to be more readily to fill the stomach."

(*Q. J. A.* vol. vii p. 456.)

6123. Comparative advantages of feeding live stock on raw or on prepared food. In 1833, the Highland Society of Scotland offered handsome premiums for reports on this subject. Five of these Reports are published in the Highland Society's *Transactions* vol. x. by which it appears that no benefit whatever is gained by the practice in the case of cattle, but, on the contrary, a loss equal to the amount of fuel and the cost of labour. Swine on the other hand afford a greater profit when fed on prepared food than on raw food. In three months pigs on steamed food increased 125 lbs. being 7 lbs. more than double while those on raw food increased only 115 lbs. being 7 lbs. more than double their first weight. Hence there can be no doubt that steamed food is more profitable for feeding pigs than raw food, more especially raw potatoes which when given alone are found insufficient for bringing a pig in a fat state. (*Transactions H. S.* vol. x p. 280.)

6124. Progress of education in rearing and breaking brute animals. The effect of gentleness in teaching the human species had not long been observed, before (generalizing on the subject) it was applied in the case of brute animals in a state of domestication, and it has been found that the domestic animals used in agriculture, and for military and commercial purposes may be trained to do their work much more effectually, and with far less labour, by gentleness than by force. This has been lately beautifully exemplified in the education of cavalry horses. The principal object in the treatment of young horses is to render them docile, and the same gentle means are now used for that purpose which are found to answer best in the treatment of children. They are rendered quiet and tractable by frequent patting, handling and rubbing them, and by taking up their feet. They are led about the barnyard to accustom them to the sight of mounted horses and to the glances of arms, and, in the course of four or five months afterwards, they are transferred to the stable, where to be trained. The good old plan, which has been followed by our ancestors for teaching boys Latin and Greek, was to whip all their sad, stupid, and of them, but kindness and common sense have at last gained the ascendancy to the great delight of the organs of sensation in both boys and horses. (*G. M. L.* 1836, p. 341.)

**2124. Training mules and horses.**—In *Ellis's Horse Training* reviewed in the *Advocate* for April 2, 1902, it is always that something into the nostrils of calves, horses, and various wild animals, renders them quite tame. The experiment has been tried in England with success; and Mr. Ellis is of opinion, that this is the secret of the celebrated Irish horse dealers, who pretended to whisper to the animal and play with his head, and thus, probably breathed into his nostrils. I have experienced quite by Mr. Ellis are founded on the following passage in Mr. Collin's work, *On the Manners and Customs of the North American Indians*:—"I have often in concurrence with a well-known nation of the country held my hand over the eyes of the calf and breathed a few strong breaths into its nostrils; when which I have, with my hunting companions, rode several miles into our campment, with the little prisoner busily following the heels of my horse, the whole way as closely and efficiently as his Indian world attach it to the company of its dam. This is one of the most extraordinary things that I have met with in the habits of this wild country; and although I had often heard of it, and felt unable exactly to believe it, I am now willing to bear testimony to the fact, from the numerous instances which I have witnessed since I came into the country. During the time that I resided at this post, in the spring of the year on my way up the river I saw of (in numerous herds of the buffalo with the Fur Company's men) in bringing in, in the above manner several of these little prisoners, which sometimes follow for five or six miles close to our horses' heels, and even into the Fur Company's fort, and into the stables where our horses were fed. In this way before I left for the head waters of the Missouri I think we had collected about a dozen. In the same way the wild horses are tamed. When the Indian has got him well secured with the lasso, and a pair of hobble on his feet, he gradually advances, until he is able to place his hand on the animal's nose and over its eyes, and at length to breathe in its nostrils, when it soon becomes docile and conquered, so that he has little more to do than to remove the hobble from his feet, and lead or ride it into camp." In confirmation of what has just been stated we quote the following:—"The taming of horses" says the *Newbern Advocate* (a North Carolina newspaper) by breathing in their nostrils, seems to be gaining friends. Mr. David Clayton of Tyrrel county having seen an article in our paper stating that horses had been tamed by breathing into their nostrils determined to try it on a certain mule belonging to him who would suffer no person to handle him. Mr. Clayton fastened him in a stable, and, after considerable trouble, succeeded in breathing several times in his nostrils. Before he left the stable the mule became gentle, and would stand still and suffer himself to be rubbed and would nose and smell around him. He followed Mr. Clayton out of the stable, around the yard and wanted to go into the house, and then he would come back to him to try the experiment. If it does not good it can certainly do no harm. (G. M. 1843 pp. 326 and 374.) The subject of training horses in this way is said to be mentioned by Meric Casaubon in his *Treatise on Equestrianism*, published in 1655, who refers to one Sullivan, a blacksmith at Cork, who practised the art. The same statement will be found in Stewart Rose's translation of *Parthénopée de Sicile* and in a note in Borrow's *Zibic in Spain*. We have introduced it in this Supplement in the hope that it may induce such experiments to be made as may set the matter at rest.

## BOOK III

### THE MINERAL KINGDOM AND THE ATMOSPHERE WITH REFERENCE TO AGRICULTURE.

#### CHAP. I.—*Earth and Soil.* (p. 319)

**8132.—3100. Humus or mould** exists in all soils and indeed is necessary to constitute soils as distinguished from rocks, which consist solely of inorganic matter. It was formerly thought that humus was soluble in water, and in that state was taken up by the roots of plants, but Liebig has shown that it is insoluble in water, and that it would soon be washed out of the soil by rains and melting snow, and that it only supplies food through the action of the oxygen of the atmosphere, with which it forms carbonic acid gas. The complete or it may be said, the absolute insolubility in cold water of vegetable matter in progress of decay (humus) appears on closer consideration to be a most wise arrangement of nature. For if humus possessed even a smaller degree of solubility than that ascribed to the substance called humic acid, it must be dissolved by rain water. Thus the yearly irrigation of meadows, which lasts for several weeks, would remove a great part of it from the ground, and a heavy and continued rain would impoverish a soil. But it is soluble only when combined with oxygen. It can be taken up by water, therefore, only as carbonic acid. When kept in a dry place humus may be preserved for centuries, but when moistened with water it converts the surrounding oxygen into carbonic acid. As soon as the action of the air ceases, that is as soon as it is deprived of oxygen, the humus suffers no further change. Its decay proceeds only when plants grow in the soil containing it, for they absorb by their roots the carbonic acid as it is formed. The soil receives again from living plants the carbonaceous matter it thus loses, so that the proportion of humus in it does not decrease. (Liebig's *Chemistry of Agriculture* 2d ed. p. 114.)

**8123.—3215. Irrigation.** Sir Humphry Davy was unable to satisfy himself as to the cause of the benefits derived from irrigation, ascribing it chiefly to the protection of the grass from early spring frosts; but if we think, with Liebig, that inorganic salts are necessary to the well-being of plants and promote an increased development of them, the explanation of the effects of irrigation with clear water becomes easy. The clearest spring water holds in solution carbonate, sulphate and chloride of lime with silicate and other salts of potash and soda. "Reeds and equisetaceae thrive in ditches and streamlets, because a large portion of silicate of potash enters into their composition, and by the frequent change of the water dissolved silice is largely supplied. The meadow grasses likewise require silicate of potash, and they are furnished with it by the water which flows over them while under irrigation. The carbonates and the carbonaceous excrements of plants contained in the soil require abundance of oxygen to promote their decay and conversion into carbonic acid. Now the water of rivers and streams holds oxygen in solution, and if, during the process of irrigation, the water be frequently renewed, no matter how thin the sheet of it with which the meadow be covered, it will communicate large supplies of oxygen, and promote the decomposition of the organic matters contained in the soil. Clearer water on the contrary retards their conversion into carbonic acid by preventing the access of air, and hence arises the sterility of bogs and marshes. In order to convert them into luxuriant meadows, it is only necessary to remove the stagnant water by draining, and where practicable, to irrigate them by means of water rapidly renewed." (Trimmer's *Chemistry for Farmers and Landowners* p. 169.)

**8144.—3217. Assimilation of crops.** The theory of the relation of crops adopted by Liebig is thus ably given in an article from by Mr. Trimmer. "Formerly the soil was supposed to contain a variety of substances, some only of which could be assimilated by one family of plants, others by another; and that each plant absorbed those substances which were suited to it, and rejected the rest. Subsequent observations caused the following modification of this theory, viz. that plants absorb indiscriminately whatever is presented to their roots in a state of solution, retaining that which is suited to assimilation by them and expelling as excrement that which is unsuited. Some experiments were made by Messrs. Pringle, in which plants were made to regenerate in a weak solution of acetate of lead, and were sprinkled

with nitrate of strontium. In each case they absorbed the substance thus introduced in, down, but it was detected by analysis in their structure, but they expelled it again. These experiments served to give confirmation of the above views, and afforded a satisfactory explanation of the fact that a plant like wheat, which contains much potash, will not flourish after potash crop harvest requiring potash, and that it thrives after clover, brass, peas, or other leguminous plants, which excrete carbonic acid, but they did not explain how land becomes fertilized by following, nor how leguminous plants cause an increase of carbonaceous matter in the soil. Other experiments, however, made by him have established the fact, that most if not all plants expel whatever their organs are unable to convert into woody fibre, starch, gluten, &c. and that these substances are of two kinds, inorganic matters derived from the soil, which are incapable of solidification and organic compounds formed in the plants by the vital process. He found, for instance, that when leguminous plants were grown in water, it acquired a brown colour, that other plants of the same kind would not grow in this water but that the plants of corn thrive in it and removed some of the colouring matter. He ascertained, too, that of the organic matters thus expelled, some were of an acid resinous nature some mild, like gums; the former of which he regarded as poisons, the latter as nutritious to succeeding crops. These organic matters thus expelled by the roots, and deposited in the soil, restore to it the carbon, which in the early stages of their growth the plants had extracted from it in the shape of carbonic acid. Before they can be converted into nutriment for other plants they must undergo decomposition. Their putrefaction must be converted into decay by the access of air which tillage produces, and then they become capable of performing the functions of humus, by affording a supply of carbonic acid. In calcareous soils the process of decay is accelerated by the presence of lime, while argillaceous soils are those in which the longest time is required for its completion. The excrements of a given crop must be thoroughly decomposed before the land will produce another of the same species and on those soils on which the longest intervals are required between crops of the same kind, it is found that the time cannot be shortened by the most powerful manures. Now calcareous soils are those on which peas, clover &c. will bear to be repeated at the shortest intervals, and argillaceous soils are those on which the longest periods are required between crops. But though these excrements, undecomposed either wholly or in part are injurious to plants of the same species as those which expelled them they are not so, nay are even capable of affording nutriment to those of other species and therefore the introduction into cultivation of every new plant which can supply the place of another such as clover or turnips, which will not bear frequent repetition confers a great benefit on the farmer by furnishing him with the means of varying and extending his rotation. (*Trenner's Chemistry for Farmers* &c. p. 196.)

## CHAP. II — MANURES.

8135 — 2294. The use of all manures is to increase the natural fertility of the soil, or to restore that which has been diminished by vegetation. The idea of a universal panacea for all plants is nearly exploded, and all the attempts to discover it are, by many considered to be on a par with the fabled of the philosopher's stone or the universal medicine. The improvements in chemistry have discovered various and different substances in every different family of plants, not only such as are peculiar to or ganized matter and are the result of the decomposition of vegetable and animal substances but others likewise, which belong to the mineral kingdom. These can be exhibited unaltered in the residue of chemical decomposition, whether in the dry way by means of heat, or in the humid way by means of the action of other substances, which destroy the cohesion of the parts and change their affinities. Thus the earths, silica, lime, magnesia, alumina, and several of the metals especially iron are found in the ashes of plants which have been burned and from the regular proportion of these in plants of the same kind, whatever be the nature of the soil in which they are raised we must conclude that they are in some measure essential to their formation. However in oiled in darkness and doubt the growth and nourishment of plants is in the present state of sciences there are certain principles which may be considered to be fully established by experiment of these one is, that whatever enters the body of a plant, whether by the roots or the pores which are distributed along its surface especially in the leaves when they are developed, must be so minutely divided that its particles are invisible not only to our naked eye but even assisted by the high magnifying powers of the microscope that is, they must be fluid, whether in a liquid or aeriform state. It is useless therefore to present to the pores, or mouths, if we may so call them of plants substances which cannot enter into them however well adapted they may be to serve as nutriment or increase. Mineral substances must therefore be dissolved in suitable liquids before the plants can imbibe them. Organic substances naturally decompose in the state of gas, and these gases may contain various matters in solution. It is more than probable that water and atmospheric air are the chief mediums in which the food of plants is dissolved; as we well know that, without the presence of both plants soon become diseased, and die. (*O C 1848, p. 67*.)

8136 The modern theory of manures as founded by Sprengel and lately established by Liebig is thus ably and concisely stated by Mr Fussy. Plants consist in the main of several vegetable substances, which are however all composed of four kinds of air variously combined these gases are named oxygen, hydrogen, carbon, and nitrogen. Dr Liebig supposes that the two first are derived by the plant from water the third, which is charcoal from the air and the fourth nitrogen, which constitutes the most nutritious part of our food, from ammonia, which substance he has found not merely in the dung of animals but in the water of rain—a new and remarkable fact. But there exists also in crops a considerable quantity of earthy matter in every ton of oat straw for instance nearly one ewt of flint whence if a dayrick be burnt, lumps of a substance like glass are often found in the ashes. These mineral substances vary in different plants as to quantity but eight are generally to be found in their ashes four of the eight being acids, namely that of flint, which is silica of bones, phosphorus of brimstone, sulphuric acid of common salt muriatic acid and also four alkalies, potash soda, lime, and magnesia. A very small quantity of alumina, or the earth of clay is also usually detected in the ashes of plants. These, Dr Liebig says cannot of course be formed in the plant but must be derived from the soil and accordingly there they are generally to be found when the soil is examined by chemistry, but in limited quantity so that the soil may become exhausted of one or more of them. But further all these eight mineral substances are to be found in farm yard dung besides ammonia, the source of nitrogen hence the excellence of dung for all crops indifferently. Some crops however require more of one ingredient than another hence the good effect of bones upon turnips, which contain a great deal of phosphorus and of gypsum or peat-ashes which contain sulphate of lime, upon clover; of Epsom salts also, Dr Liebig states which contains magnesia, upon potatoes. Some soils, again may contain so much of one of these eight minerals, that it may be useless to add any more. Thus gypsum is found to be useful in one part of a field and not in another and bones are useless in Mecklenburg, where the fields are dressed with a man full of phosphorus, or on the other hand, a tract of country may be deficient altogether in some one of the eight ingredients which is necessary for all crops, as in lime. In such a district lime will be a standing measure. This new theory of agriculture, though but a theory at present, certainly promises important results. In order to test it first, and, if it hold good to apply it afterwards, two courses of inquiry are requisite. 1. as Dr Liebig informed Mr Fussy, a more minute examination of the ashes of plants in which these mineral substances are found, and further a more accurate analysis of our

various soils, in which the particular English science is sadly defective: *See*, Dr. Liebig's *phosphorus*. Dray has made several analyses of various fertile soils, and since his time numerous other analyses have been published, but they are all so superficial, and far-most cases so inaccurate, that we possess no means of ascertaining the composition of nature of English arable land. This remark on our science certainly is not a new one, and it is easy to see how varied a field of inquiry is opened by the new theory" (*Journal*, N. S. S. S., vol. III. p. 314.)

6177 On the practical application of manures. Mr. Fane has given the following summary of the result of several experiments. On this most difficult subject in agriculture, manures, "It may be said that we have learnt a great deal in the last four years, but know nothing; for we have learnt many of the theoretical principles on which manures act, but we do not yet know how to apply those principles to the daily work of the farm. It is now established, that the most important ingredient of farm-yard dung is ammonia; the same substance as common smelling salts known to escape very readily in the air and there is a growing opinion that a great deal of it does so escape from our farm-yards; which is doubtless the case; though I am not sure whether the alarm on the subject be not somewhat exaggerated. For ammonia acts chiefly from the urine of the cattle, but it does not form itself until after some days and by that time, in a well-tended yard, it has sunk from the surface, and has been trampled down, so that it can less easily evaporate. Whilst it is forming itself, too, the straw begins to decay; and it is the opinion of Sprengel that an acid, called the humic acid, formed from the decaying litter, has the property of combining with the ammonia, and removing its volatile property. This must be doubtful of course, and various means of fixing the ammonia have been proposed. Sulphuric acid is one, either in the shape of gypsum, which has been found not to answer or in that of green vitriol, or as a pure acid; but these are at present only suggestions. We have been also strongly urged to imitate a foreign practice of using liquid manure, spread from a water-cart but this I believe to be a very doubtful innovation. For if the urine be collected separately it is the opinion of Sprengel that a still greater escape of ammonia takes place, unless some substance, which is not yet ascertained, be added to it, or unless it be largely diluted with water, which consumes great labour in its application. This has objection has also against the other form of liquid manure the runnings from the yard collected in a tank, for after heavy rains they sometimes do not contain above two per cent. of salts, and are then not worth the labour of carriage. It appears that this foreign practice has arisen from two causes one the want of litter and where the same cause exists, as on some of our dairy farms the method might be well introduced the other motive is, the desire in Flanders of applying a liquid top-dressing in May to the corn growing on sandy land, or also to a second crop, such as carrots soon amongst others. But in this case does not arise in England. Some low, however, must arise by the runnings from every farm yard; so whether the ammonia be fixed or escape in the air there is no doubt it is still soluble and runs away in the water. But "if the yard be well littered, and the dung-hill be covered with earth I doubt whether excepting on grass farms, where the tank may be necessary from the want of straw the present management of dung can be greatly improved, though in many districts the quality certainly may be improved."

6188 Artificial manures or hand-tillages. Besides farm yard dung we have an indefinite variety of artificial manures or hand-tillages indeed, it may be said that there is no refuse of any trade provided it be animal or vegetable, except tanner's bark, which is not or might not be used for this purpose. It would be useless to enumerate all as they are well known, and the supply of many is very limited. The two principle articles are bones and rape-dust, the former suited for light land, and used chiefly for turnips. It is remarkable how very local is the use of both these manures, that of bones, indeed, is spreading, but rape-dust is not so much known in the south, and certainly where artificial manures are new there is some unwillingness to lay out money upon them though dung perhaps is bought at the cart-hill, and carted with great labour at a long distance. When bones were first used it was thought that uncolled bones must be better than those from which the animal oil had been extracted; but the reverse appears now to be true — not that animal oil is useless but that it weakens probably the bones, and checks its action upon the plant. There remains however in the bone another animal compound, gelatine or the matter of jelly but Sprengel states he has repeatedly found that bones act as strongly after they have been burnt, when the jelly of course is removed and this is well worth remarking, because the body of the bone consists of phosphate of lime, evidently another powerful principle, which is found also abundantly in urine, and consequently in dung. But though the character of bones is established upon light land for turnips, even this manure fails on some soils of that quality which shows that we cannot be too cautious in prescribing even the most approved remedies for the first time upon land.

6189 A *slaps-dust* appears to be established chiefly among the farmers of Nottinghamshire, Yorkshire, and Lancashire. As it is one of the few hand-tillages which can be applied to clay and as some of our south-country clays are much in want of assistance, I may mention that, according to an excellent prize essay of the Wetherby Agricultural Society by Mr. John Hamman the best mode of using it is drilling with autumn-sown wheat at the rate of 4 or 5 cwt to the acre the price being about 7 per cwt.

6190 *Rags*. Mr. Hamman states, "30,000 tons of rags are sold to be used annually by the farmers of Kent, Sussex, Oxford, and Berkshire. The price is about 14 per ton. They answer extremely well for hops and wheat. They are usually cut by a chopper into shreds, and applied by the hand at the rate of half a ton per acre." Six or seven cwt is considered a fair dressing for wheat upon light land on heavy land rags are not used at all.

6191 *Nitrate of soda*. From which so much was once expected, has given various and contrary results. There are the most undoubted proofs from numerous quarters of an enormous increase in the produce after its use. There are as undoubted instances of its utter failure, nor have we any clue to the mystery. A full statement of all the recorded experiments on nitrate of soda is contained in Professor Johnston's *Chemistry and Geology applied to Agriculture*, the most complete account of agricultural chemistry that we possess. On the same land where it gave Mr. Fane 5 bushels of wheat one year it gave barely 1 in the following, and having tried it largely at that time on four different farms, nowhere with success, he has given it up. Still there is evidently a principle of fertility in it, which will some day be found out, and some farmers continue to use it but in several cases it has produced mischief in wheat and barley by forcing the crop beyond the strength of the land. By the side of the nitrate Mr. Fane tried on several fields the sulphate of ammonia, extracted from gas-water for the first time. It acted precisely as the nitrate of soda, darkening the colour of the plant, and lengthening the straw and the ear even more than the nitrate but it certainly did not pay. Again we have the principle, and we must learn to combine it."

6191 *Guanos*. "I can speak with more confidence of the last new manure, guano, having used it on a small scale last year, and to the extent of 5 tons in the present season. There are two circumstances in its favour before-hand: one, that it is in fact dung, though of very ancient origin, and birds dung which is known to be the most powerful of all manures; the other that it has experience in the favour, though a distant experience certainly at the other side of the globe, in Peru — still an experience of 300 years. It appears to be best calculated for root-crops. On a light loam, where it has been used here this year for turnips at 3 cwt. to the acre, costing 15s. it has nearly equalled 30 loads of very good dung, and has beaten 20 bushels of bones costing 15s. as well as several other artificial manures, beyond any comparison. It has failed as a top-dressing on corn and on clover. On the whole, guano seems an excellent manure for root-crops, if rightly applied, and, as it is now sold at 12s. the cwt, a very cheap one; but I should be sorry to hear of it being tried largely on a different soil than light loam without success."

6192 *Guano* is so largely used on the west side of England that it bears there the name of

manure. Whether it could be adopted elsewhere, with the same advantage, is a very interesting question, as is the mode of its application. "The H. Davy's theory that it dissolves vegetable matter, is given up. In fact, it hardens vegetable fibre. Some persons think that it should be applied hot to the soil, founding their view upon chemical principles, but at present it seems better to follow practice, and where it has been mixed heretofore with five times its bulk of earth, and left so in heaps for some weeks before it is applied to the surface, it would be well to do so still. Dr. Liebig has recently discovered that lime has the power of decomposing clay and producing potash and soda, which are fertilizing principles. Now, if this be the mode in which lime acts, there could not be a better course than to mix lime with earth before it is thrown upon grass land, and the old practice would agree with the true theory as it often the case. Of all things we must guard against premature inferences from abstract science, but, in the course of time, the effect of lime in sweetening sour pastures is wonderful throughout the districts where it is used; and it is well worth inquiry whether it could be applied in those districts where it is at present unknown. (*Journal R. A. S. E.*, vol. III. p. 318.)

8143. *The new salts and other manures.* Numerous trials have been made within the last seven years with salt, nitrate of soda, ammoniacal hay, and other ingredients of comparatively little bulk, as manures. An estimate of the value of the present state of our knowledge on the subject has been made by an eminent practical agriculturist and rent-paying farmer Mr. Oliver of Scotland, from which the following extracts are taken. Mr. Oliver has long been of opinion that "by the discovery of new fertilizing substances, a great and fresh impulse may be given to agriculture."

8144. *The great desideratum in agriculture hitherto has been to keep up and increase the fertility of the soil by returning to it, in the form of manure, more food for plants than has been carried off in the form of crops and the excrements of agriculture has been in proportion to our means of economy in this object. The introduction of turnips and other green crops has, within the last 100 years added to the weight of materials produced by a farm capable of being converted into manure in the proportion of 18 to 1. Notwithstanding this, the proportion of grain crops which can be advantageously taken from land of the first, second and third degrees of fertility in situations where no considerable supply of excrementous manure can be obtained does not exceed three two-fifths, or two-sevenths respectively, whereas, on lands in the immediate vicinity of large towns, from which an abundant supply can be had, one half, and, in some instances, such as frequently occur in the neighbourhood of Edinburgh, three-fifths are advantageously devoted to that purpose. If then, fertilizing substances which can be transported at a moderate expense to those districts distant from large towns are discovered, the proportion of land so situated which may be annually allocated to the production of corn will be greatly increased. If, for instance, by means of a sheep top-dressing, such as nitrate of soda or ammoniacal water, land which is now under the six shift-course, and consequently three years under pasture in each rotation can be made to feed three bullocks instead of two it is obvious that such land will be nearly as much enriched, though left only two years in pasture, as it was formerly when three years and might therefore be brought under the five instead of the six shift-course by which two-fifths could be annually devoted to corn crops instead of two-sevenths. In like manner if by means of a similar top-dressing, land which formerly required to be two years in pasture can be made to maintain double the number of sheep or bullocks, the period of pasture might be reduced from two to one year by which means one-half, instead of two-fifths, would be annually under corn crops; and in the case supposed, 60 bullocks would be grazed on a farm of 100 acres instead of 40 while the extent of land under corn-crop would be 60 instead of 40 acres with little or no chance of the acreable produce being diminished.*

This, it will be observed, would be the result simply of discovering substances adapted for top-dressing grass lands, and having the effect supposed in the preceding remarks. But if we should be fortunate enough to discover also other substances equally efficacious when applied to potatoes, turnips, and corn crops, the means of human subsistence would be still further augmented in proportion to the fertilizing power of the substances applied.

Mr. Oliver next asks, 1st. What probability exists of obtaining the object sought? and 2d. By what means are we likely to prove successful?

As to the probability of discovering new fertilizing substances it may be observed, 1st. That the recent and rapid progress which has been made in chemistry and vegetable physiology as regards their application to agriculture, has drawn the attention of several distinguished scientific gentlemen to the subject. 2d. We are not in search of a substance, such as putrescent manure, possessing fertilizing powers in almost every soil and situation and for all and every description of crop (we are therefore to the suggestions of science) in search of specific substances adapted to specific soils, situations, and crops, thus increasing our chance of success in discovering the object of our search and diminishing the chance of its becoming exorbitantly high priced, if found. 3d. The experience of practical agriculturists, so far as it goes, is at least encouraging. Of several new substances tried as manures of late years two at least rape and bone dust, may be said to have fully succeeded. Others are under trial, with greater or less probability of success, and it may not be uninteresting to give the results of some recent experiments as illustrative of the progress already made in that department.

An account of experiments by Mr. Bishop overseer to Mr. Smythe, of Metheren, shows the effect of nine parts of soda, rape dust ammoniacal water, and a mixture of nitrate of soda and common salt, applied as a top-dressing to three years old pasture in summer 1841. Five Scots acres were subjected to experiments, not for the sake of ascertaining the comparative effect of the manures applied, the whole was reserved for hay and the produce contrasted with that of an adjoining acre, to which nothing was applied. The expense of the top-dressing in each case was about 12. 1/2 per Scotch acre. The effect of the three first-mentioned substances was so nearly the same as to render any distinction unnecessary. The result per Scotch acre may therefore be thus stated —

The three acres to which nine parts nitrate of soda, and rape dust were applied, produced on an average each 574 stones of hay, the acre to which ammoniacal water was applied, 410 and the acre with no top-dressing produced 136.

It thus appears that the additional produce from the three former manures was 136, and from the ammoniacal water 574 stones per acre being in the former case exactly double, and in the latter nearly treble, the produce yielded by the acre to which no manure was applied, and taking the value of such hay at 6d. per stone, gives a profit of 17 1/2 sh. on each of the former and 35 sh. on the latter per acre. The profit from the ammoniacal water is very striking, but Mr. Bishop in some measure accounts for it, by stating the interesting fact, that the growth of timothy grass, of which the pasture partly consisted, was promoted in a remarkable degree by its application, whereas the other manures did not seem to promote its growth more than that of the other grasses in the field. This result tends to strengthen the opinion, that specific manures applicable to specific crops exist, and that the discovery of them will prove beneficial to agriculturists.

In an account of experiments furnished to Professor Johnston, of Durham, in consequence of suggestions granted and circulated by him last spring, results, on the whole satisfactory and, in many respects, highly encouraging were also obtained, a few of which it may not be uninteresting to state shortly referring those who are interested in the subject to the pamphlet (*Experimental Researches into the Principles of Agriculture*, pamph. 8vo. 1841) for a more detailed account, and Mr. Johnston's remarks on the experiments individually.

Near Aske Hall on the property of the Earl of Rutland, six bushels of common salt, which cost 12s. applied to clover and rye-grass hay gave one ton of hay of additional produce per imperial acre, which, at 24s. per stone, is worth 24. 0s. 0d., leaving on profit, after deducting the cost of the manure, 12. 0s. 0d. per imperial acre, 35. 7s. 6d. per Scotch acre: 30 bushels of soot, which cost also 12s., gave an increase of 10

cwt., or 80 stones, worth, as above, 3*l.* 11*s.* 6*d.* of nitrate of soda, which cost 1*l.* 2*s.*, gave 12 cwt., or 80 stones additional produce. The same quantity of sulphate of soda, which cost 2*l.*, gave 5 cwt., or 30 stones.

In a similar set of experiments made at Erskine, the property of Lord Elphinstone, near Glasgow, with a variety of substances applied, also as a top-dressing to clover and rye-grass hay partly on light and partly on clay soil, *surprising* results were obtained, especially on the light land, 120 *lb.* of nitrate of soda having given an increase of one ton of hay per imperial acre the same quantity of saltpetre or nitrate of potash gave 120 cwt. The effect, however, on the clay land was less in every instance, 10 cwt. being the present additional weight of produce obtained, and that from nitrate of potash. Nitrate of soda yielded 9 cwt. 1 qr. 12 *lb.*, being rather less than half the quantity obtained from its application to light lands.

Mr Fleming, of Berriechan, obtained also nearly equally favourable results from the application of nitrate and sulphate of soda to clover and rye-grass hay though he seems to have applied the latter in only half the quantity suggested by Professor Johnston. 120 *lb.* nitrate of soda gave 1 ton of additional hay per imperial acre, and the same quantity of sulphate of soda about 8 cwt. only.

Mr Fleming gives also a tabular view of experiments on a field of wheat with a considerable variety of manures, on which Mr Johnston makes the following remarks:—"This table presents us with two remarkable results that obtained by the use of common salt, and that from a mixture of soda and repeat. Thus exclusive of the straw

"Nitrate of soda alone gave 120 *lb.* of wheat for 3*l.* or 1*l.* 2*s.* per bushel

"Nitrate with rape-dust gave 200 *lb.* of wheat for 4*l.* 6*d.* or 6*s.* 6*d.* per bushel

"Common salt gave 472 *lb.* of wheat for 3*l.* 6*d.* or 6*s.* 6*d.* per bushel.

The increased produce by the use of common salt is by far the most valuable result to Mr Fleming, in an economical point of view, and plainly indicates the kind of application he can most profitably make to his wheat crops, at least on land similar to the above and in the district where he resides.

"Neither the nitrate of soda, nor the mixture of this salt with rape-dust, gave such an increase as to repay their own cost, unless wheat corn is very high. It is interesting, however, to observe that the mixture with rape-dust gave so large an increase though the value of this particular experiment is lessened by the absence of any trial with rape-dust alone, by which the effect of each of the ingredients ought to be judged of. I have reckoned the rape-dust at 7*s.* a ton so that 5 cwt. would cost 3*l.* and we know that a top-dressing of this substance alone, in a somewhat larger quantity gives a remunerating return in many of our wheat lands."

Mr Fleming's experiments on oats, potatoes, &c. afford equally interesting results, and are deserving of the attention of all who feel an interest in agriculture, but I shall confine myself at present to that made on early potatoes in 1841 which cannot be more clearly or shortly stated than in Mr Fleming's own words.

"All were dug in the usual manner with farm yard manure, at the rate of about 80 cubic yards per acre. The potatoes were all planted on the 24th of March on the same *Acres black soil*. The several dressings were applied on the 30th of May and the potatoes were all lifted on the 28th of September.

2	Nitrate of soda	120	66	77	24
3	Sulphate of soda	200	73	85	7
4	Ditto and nitrate of soda	300	107	124	41

*Note.*—The peck is 35 *lb.* weight, and 16 make a boll, or 5 cwt.

"This break of ground consists of a piece of poor clay mixed with moss, about 9 inches deep subsoil a very stiff blue till. The dung was old from the farm-yard, about the ordinary quantity (30 cubic yards per acre) spread upon the land and dug in. The potatoes were drilled in a 15 in. hole as the ground was wet the plants came up but weak. The nitrate of soda was sown before the other top dressings, and had remarkably quick effect, as it showed the third night after being sown. The sulphate of soda does not occasion the dark green colour which is seen upon the potato after the dressing of the nitrate but there is not the smallest doubt of its beneficial effects, although not so great a degree as the nitrate. The mixture, which is composed of two-thirds of sulphate of soda and one-third of nitrate, has a wonderful effect in strengthening the growth (which it keeps longer than with nitrate alone), and the mixture has the same effect in producing the dark green colour as the nitrate alone.

Professor Johnston is remarking on this and similar experiments furnished by Mr Fleming's gardener observes: "Those who are the most sceptical in regard to the benefits to be derived from agricultural experiments when well conducted, will scarcely question the importance of this result the most backward in making experiments will be anxious to repeat this upon his own potatoes. The cost of the mixture to be applied in the quantity used by Mr Fleming is as follows:—

Sulphate of soda, 75 *lb.* dry at 1*s.* per cwt. or 180 *lb.* in crystals, at 5*s.* 6*d.*  
Nitrate of soda, 75 *lb.* at 1*s.* 6*d.*  
5*s.* 12*d.* 9

5*s.* 12*d.* 9

The return for this 5*s.* 12*d.* 9 was in each of the above cases upwards of 3 tons of potatoes.

Though the number of experiments made, and inferences which can be safely deduced from them, are far too meagre to admit of our feeling confident of success, yet it may perhaps be admitted, that they are such as to hold out sufficient encouragement for further prosecuting the inquiry.

This I apprehend, can only be successfully done by the united efforts of the practical and chemical agriculturists; the former by instituting and carefully conducting experiments on a systematic plan the latter by tracing the facts so obtained to the laws of nature on which they depend, and the progress with all probability be in proportion to the number of practical men who can be induced to engage in making the experiments with precision and accuracy. It would be advantageous I apprehend, in all cases to analyse the soil to be experimented on and to ascertain by weight the kind and quantity of the material to be applied, as well as the quantity and quality of the produce obtained from the application of each description of manure. This, however, is an inquiry which cannot be successfully prosecuted by a few individuals, nor can satisfactory results be obtained from a small number of experiments. Diversity of soil, climate, direction, season, and a variety of other circumstances combine to throw doubts on results so obtained, however carefully conducted. But this should not deter us from prosecuting the inquiry; on the contrary it is an additional reason for all who have it in their power whether owner or cultivator, contributing their share."

Mr Ormer concludes: "Assuming, then, that the object in view is of sufficient importance to merit the attention of this Society and that the few experiments which have already been instituted hold out sufficient encouragement for expecting a successful result, I trust I shall neither be considered pro-

complaints nor ever sanguine in expressing my hope that the Society will give the subject their best consideration, and afford such aid as may seem to them best calculated to secure the co-operation of practical agriculturists, in instituting and reporting the results of experiments, carefully made on a regular and systematic plan. We may not succeed to the full extent; but I cannot help thinking that a wide, fertile, and unexplored field to agricultural improvement lies before us; and although it would be rash to venture an opinion as to the results which the combined effect of sciences and enlightened practice may arrive at, it would be equally rash and less politic, I apprehend, to rest satisfied with our present knowledge. Let practical men, therefore establish facts by experiments, carefully made, whether from the suggestions of their own mind or those of others; and let the duty of tracing these to the principles of nature on which they depend, be seasonally discharged by men of science; and perhaps the progress may be more rapid and the success greater than it would be either wise or prudent to anticipate at present. (*Trans H S.*, vol. xiv p. 625.)

8146 *Experiments with saline manures*, made on a farm in Essex, gave the following results which may be depended on for their accuracy. "A field of wheat was chosen which in the latter end of April, 1842, presented a thin plant; the salts were top-dressed over the land, by hand, on the 13th of May and the crop mowed on the 10th of August. The soil was rather poor consisting of a heavy clay upon a sub-soil of the London clay. 1. No manure. corn per acre, 1412 lbs. 2. With 20 lbs. of sulphate of ammonia corn, 1613 lbs. 3. With 140 lbs. of the same salt. corn, 1695 lbs. 4. With 112 lbs. of nitrate of soda; corn, 1605 lbs. 5. With 112 lbs. of nitre corn, 1800 lbs. The fourness in the straw was also considered able in all cases except with the small proportion of sulphate of ammonia. The total increase in the four measured crops was per cent in the order in which they were enumerated, 141 41 8, 24 and 28 5; the cost of the manure for the three last did not greatly differ being 21s 6d, 24s 6d, 27s 6d. The profit on the outlay was, with the small dose of sulphate of ammonia, 294 per cent with the large dose 312 per cent; with the nitrate of soda, 120 per cent and with the nitrate of potash, 92 per cent. The principal conclusions drawn by the author are, that the increase of the nitrogen in the crop is greater than is accounted for by the nitrogen of the manures, showing that these manures have a stimulating effect or enable the plants to draw additional nitrogenised food from the soil and atmosphere; the considerable superiority of sulphate of ammonia over the other salts and the greater proportional efficiency of a small than of a large dose of that salt. The sulphate of ammonia costs 17s per cwt. It appears best to apply this salt in the proportion of about 1 cwt per acre as three different dressings; the first quantity sown the crop, if wheat, makes its spring growth or if of oats, when about two inches above the ground, the second quantity about a month afterwards and the third quantity at the time of the formation of the ear. To meet the practical difficulty of distributing so small a quantity as one third of a cwt. over an acre, about twice the quantity of common salt or of soot may be mixed with the ammoniacal salt. These and most saline manures when used as top dressings should be supplied to the plant when dry some time after a shower of rain or during busy weather." (*G C* 1842, p. 533.)

8146 *Ammoniacal salts as manures*. In Switzerland water is poured over the fresh stable-dung so as to wash it; the fluid thus obtained is saturated with sulphate of iron, or sulphuric acid, and a liquid manure of great power is the result. It has for many years been the custom in Switzerland to preserve stable urine, to wash the fresh manure, and to collect the fluid in reservoirs, where after fermentation has taken place, the ammonia is saturated and converted into sulphate of ammonia by sulphate of iron (green vitriol), sulphate of lime (gypsum) or sulphuric acid (common vitriol). The fluid thus obtained when employed for watering land, produces a strong vegetation an effect that is ascribed to the sulphate of ammonia, which is not volatile like the carbonate if acted upon by the sun. Fresh manure, like urine contains ammonia, which it is important to preserve, but which is generally washed by the common modes of managing manure. (*G C* 1842, p. 191.)

"Dr Sprengel, after describing the various methods of employing liquid manure uses these strong words — Whoever is obliged for want of straw to collect the urine separately — whoever if he be compelled to do this, mixes no water with it, or who fails also to employ some neutralising substance to combine with the ammonia, which is produced in so great a degree during the summer — suffers a loss of manure which exceeds all belief. It is, indeed, only a gaseous substance and not a solid material visible to the eye which thus escapes and is lost; but for all that, it is of greater importance to the plants than any other portion of the droppings (*Journ A S E* vol. iii p. 208). The quantity of sulphate acid required to fix the ammonia of urine in a state of putrefaction is 12 per cent; of muriatic acid, 34 per cent; or by weight, 12 lbs. of sulphuric acid 34 of muriatic acid, or 124 of sulphate of lime to fix the same quantity of ammonia. (*G C* 1842 p. 31.)

8147 *To ascertain whether or not a liquid contains free ammonia*. Take a tea-spoonful of common turmeric powder and mix it into a thin paste, with a little water. Keep aside one-half of the greenish yellow paste thus formed and mix the remainder with three or four times its bulk of the liquid to be examined. If it contain any free ammonia, the liquid becomes immediately of a reddish brown colour the depth of the colour depending on the quantity of free ammonia it contains upon the addition of a few drops of any acid the ammonia will be neutralised, and the turmeric will return to its original yellow colour. The value of any acid or other substance as a fixer of ammonia may be well tested in this manner. The liquid must be mixed with a little of the powdered root which it will immediately reddish. The value of the fixer or the quantity of it required for any quantity of the manure is known by observing how much of it must be added to bring back the original yellow colour of the turmeric. Turmeric root may be procured at almost any chemist's. If only the whole roots can be obtained they are readily rubbed to powder on a common grater like ginger. (*E Solly* in *G C* 1842 p. 868.)

8148 *Test for the presence of Ammonia*. A strip of paper previously rubbed over with petals of the common mallow will be turned green if the ammonia predominate in the liquor. The absence of the ammoniacal smell is a very uncertain proof of the saturation of the ammonia by the sulphuric acid, and the use of the test will save the waste of acid. (*G C* 1842 p. 742.)

8149 *Nitrate of Soda*. The effect of this manure in increasing the value of the hay crop, has been strikingly exemplified in numerous instances. Mr Grey of Dilton, dressed one portion of a field with nitrate of soda another portion with manganese and nitrate of soda in equal quantities, and a third portion was left without any dressing. This was done in May at the expense of 25s per acre for the nitrate of soda and 15s for the nitrate and manganese, and when the hay was made the produce was found to be 2 tons 20 stone in the former case 3 tons and 21 stone in the latter and only 2 tons and 37 stone on the space which received no dressing. (*Trans H S* vol. xiv p. 380.)

8150 *Natural effluvia of potash for manure*. Potash being drawn from the soil by every crop, requires constant renewal. The ordinary resources are vegetable ashes of different kinds, such as wood, some kinds of peat turf, weeds, leaves, and even straw. The potash in the feed both of man and beast is restored chiefly in the form of liquid excrement which runs to waste in our towns as well as in our farm-yard drainings. Liebig proposes to procure the effluvia of potash from the ashes of burnt wood but Mr Pridemore an eminent Plymouth chemist, suggests the idea of obtaining it from Dartmoor or other granite by burning and mixing with lime. The details of the process will be found in the *Proc. F M N S*, vol. vii p. 102.

8151 *Effect of mixed manures*. "It is probable that one of the reasons why natural manures are so much more valuable than any of the simple manures, in their consisting of many different ingredients, so that if one does not take effect upon a crop, another may. Thus we see that farm-yard dung, guano, cloacina, and compost-heaps produce invariably a good effect; while nitrate of soda, sulphate of lime, and the other saline ingredients now so extensively employed, sometimes succeed, sometimes fail, and always succeed best when used in addition to the ordinary manures. Experiments show that plants are not little

improved by simple manures when they can get nothing else, and that it is only when the soil is so rich that they grow too luxuriant, and still require a quantity of the organic matter of fermentation, that the effects of simple manures become disadvantageous. This is in some amount corroborated by certain valuable experiments made by Mrs. Fleming, of Berwickshire. On a soil which, without being recently cultivated, produced 4 tons of the best turn potatos, 35 bushels of wood-ashes (which were as regarded as a simple manure) raised the crop only three quarters of a ton at the expense of 5s. 10c. 4 cwt. of natural guano, a very compound substance, added more than 7½ tons, at the total cost of 55s. (reckoning guano at the present price). But when 15 bushels of wood-ashes were added to 4 cwt. of guano, the crop rose again 1½ ton further at the additional cost of 12s. 6d. So that, where wood-ashes were used alone, the small quantity of potash obtained by them cost 4s. 4d. a ton while, in combination with guano, the same substances furnished potash at the expense of only about 2s. a ton. To the guano and wood-ashes 20 bushels of charcoal were added, at a cost of 7s. 6d., and the effect was to add 1½ ton more to the crop, so that now the additional crop cost scarcely more than 4s. a ton. This may be stated a little differently in the following manner. — Where wood-ashes (a simple manure) were used alone, the potatos obtained beyond what the land would yield without any manure whatever cost 12s. 6d. per ton. But where wood-ashes were used in addition to more complicated manures, the crop was largely augmented, at an expense in manure amounting only to from 6s. 6d. to 10s. 6d. per ton of extra produce. These things seem to prove conclusively that the best way of using saline or simple manures for the potato-crop is to apply them in addition to common manures, and not on any account to trust to them by themselves. (*G. C.* 1843, p. 243.)

8162.—8163. *Guano in South America* is scarcely used but on land where maize and potatoes are cultivated. It is applied to both maize and potatoes when about 2 ft. high, at the rate of a single handful to three different loads of plants. Wheat must be sown within two or three days after the guano is applied. (*North Lane Express* as quoted in *G. C.* 1843, p. 175.)

8164. *Potter's artificial guano.* Mr. Cotton, of Hildersham Hall, near Cambridge, used it for barley and obtained 6 quarters per acre; on grass land the ordinary produce of hay was doubled. On orange mangel-wurzel the result was still more striking, a square yard dressed with common three-yard manure produced 25 lbs.; another dressed with Potter's guano 40 lbs.; the heaviest root of the latter weighed 19½ lbs.; others 12 lbs. and 15 lbs. The soil was light, with chalk close to the surface. At the rate of weight obtained by Mr. Cotton, 17 tons an acre of mangel-wurzel were produced, which is more than double the usual maximum; and the result of an experiment by Lord Epsom, showed that artificial guano may be employed on grass land with very decided advantage. (*G. C.* 1843, p. 2.) Potter's guano is commonly mixed with two or three times its bulk, with chindr stinging, charcoal powder or peat, soil, or other manure.

8164.—8165. *Cloacine may be destroyed by earth which is very rich in vegetable matter and by mud from ponds.* (*G. C.* 1843, p. 285.)

Cloacine and Epsom salts, recommended by Liebig as a powerful manure for potatoes. One ton of cloacine without Epsom salts equal to six tons of the best farm-yard manure. (*G. C.* 1843, p. 28.)

8165.—8167. *The treatment of stable dung by M. Schutzenmann of Bouxwiller in Alsace* is thus described by himself: "I have for many years been in the habit of treating stable-dung in a manner entirely different from that commonly in practice. At Bouxwiller I have had for several years the control of the stable-dung of 300 artillery horses quartered there in a single building at the back of which lies some land of my own. There I have formed a trench for manure occupying 800 square yards superficial and divided into two equal parts. This trench is an inclined plane which rises forward and right and left, so that all the water which enters it runs down to the middle, where it collects, as that place I have a pump, by means of which I am able at pleasure to return to the manure the water which runs away from it. What water I want, I obtain from a well and pump placed by the side of the manure trench. By these means, at a trifling expense I obtain that great quantity of water which stable-dung requires while at the same time I do not lose a drop of the saturated fluid, which eventually is altogether absorbed by the manure by the time that it is taken away unless I prefer employing it directly and to replace it by pouring more pure water over the manure. Ten halves of my trench are alternately filled from the wheels. The litter is made up six or eight yards high over the whole surface of the excavation trod down by the feet of the men who bring it and spread it, and abundantly watered by the pumps. In this way I have it thoroughly made up and as much water as I want, two conditions which I consider indispensable, in order to counteract the violent fermentation of the stable-dung, which would destroy the most active parts of the manure, which are volatile. I add to the saturated matter and I scatter over the manure green vitriol in solution, or gypsum so as to change into a sulphate the ammonia as it is produced, and which readily flies off at a slightly elevated temperature. By means thus simple and cheap I obtain in two or three months a mass of manure thoroughly made as soft and pasty as that of cattle, and of great energy as is proved by the remarkable results I have obtained both on arable and meadow land for several years. When this manure, or the liquid which flows from it, is applied to land, the most striking effects are apparent. Litters formed upon a meadow by pouring it from the spout of a watering pot, speedily acquire a deep rich green, remarkable among the surrounding herbage. It is, however, necessary, in forming such dung-hills, that they should be so placed as to allow the water to run completely off them, and that they should be frequently drenched. Farmers do not employ anything like the quantity of water required to decompose stable-dung. Care also must be taken that the litter is thoroughly trodden down by men and horses, so the dung-hills are made, partly in order to enable it the better to retain its moisture, and partly to check the excessive heating which drives off the best parts of the manure." (*G. C.* 1843, p. 191.)

8166.—8168. *Calcareous manures.* Mr. Ruffin, a scientific agriculturist of great repute in the United States, has made many experiments with calcareous manures, and has proved the following propositions, which would appear to contribute much to the clear elucidation of the causes of the fertilizing effects of lime:

1. That soils naturally poor and rich soils reduced to poverty by cultivation, are essentially different in their powers of retaining putrescent manures; and, under like circumstances, the fitness of any soil to be enriched by these manures is in proportion to what was its natural fertility.
2. That the cause of the natural sterility of the soils of Lower Virginia is their being destitute of calcareous earth, and their being injured by the presence and effects of vegetable acid.
3. That the fertilizing effects of calcareous earth are chiefly produced by its power of neutralizing acids, and of combining putrescent manures with soils, between which there would otherwise be but little, if any, chemical attraction.
4. That poor and acid soils cannot be improved durably or profitably by putrescent manures, without previously amending them calcareous, and thereby correcting the defect in their constitution.
5. That calcareous manures will give our worst soils a power of retaining putrescent manures, equal to that of the best.

The proofs of these five propositions will be found at length in the *Annals of Agriculture*, vol. vii p. 141.

8167.—8167. *Unimproved compost.* The following ingredients and quantities, it is said, will afford a sufficient density for the use of land. Fifty gallons of vegetable alkali or English Russian, or American potash; thirty-six pounds, viz., four gallons of oil of any kind; one hundred and twelve pounds, viz., two bushels, of common salt; fifty pounds, or about a bushel, of quicklime. Mix the whole together, the alkali and salt having been previously dissolved in water and reduce the whole to such a degree of fluidity that it may be poured from the spout of a watering-pot on as much light porous soil as will absorb it. After this compost has lain some days, it may be turned over, and spread over the soil

to be measured; but if there is a proper under-est, this measure may be applied over the land in the next year. (See *A Dissertation on Soils and Manures*.)

1116 *List of Aerial manures offered for sale at the present time (July 1862) in London:—*

Agricultural salt	Super-phosphate of lime
Agricultural salt, fine	Potters' blacking mixture
Alexander's compost	Potters' concentrated mixture
Blackening powder	Super-dust
Bone dust, and half-bark bone	Rock salt
Briarstone	Saltpetre per cwt. (duty paid) 3s 6d. (See Petro, salt)
Clark's dedicated compost	Silicate of potash
Daniell's Bristol manure	Soda ash
Gusno, foreign	Sulphate of ammonia
Gusno Potters' English	Sulphate of iron
Gypsum	Sulphate of soda
Humphrey's inodorous soluble compound	Sulphur
Linne's new fertilizer	Sulphuric acid
Imperial compost	Trimmer's composition for clover
Muriate of ammonia	Trimmer's composition for wheat, with silicate of potash
Muriate of lime	Trimmer's compost for turnips
Nitrate of soda	Urate
Petro, salt, 4l per ton (See Saltpetre)	Watson's compost for turnips.
Phosphate of ammonia	In all thirty-eight sorts!
Phosphate of soda	
Phosphate of lime	

1119 *Estimate of Aerial manures* "Liebig," says Professor Johnston, broadly announced that wheat grows well in this soil, because it contains much potash, refuses to grow in that, because potash is wanting, and that the efficacy of a fallow consists in its allowing the potash of decaying minerals to accumulate in the soil and thus to provide a sufficiency for an after crop of corn. What was this, but to say that, by adding potash to the soil, you may grow wheat after wheat for an unknown period? How important, and yet how simple a discovery this! No wonder that it attracted the attention, and excited the hopes, even of the more instructed farmers, and that a kind of potash mania should have spread among the distressed agriculturists from one end of the island to the other. Then was the flood-gate opened for new varieties of quackery, and every large town speedily produced its own chemical manure manufactory" (*Q. J. A.*, vol. 1 N 8 p 7)

## BOOK IV

### MECHANICAL AGENTS EMPLOYED IN AGRICULTURE.

#### CHAP. I.—*Implements of Manual Labour used in Agriculture* (p. 369.)

1110—1144 *London patent spade* has the blade case hardened, so as to remain much longer sharp than the common spade which is apt to wear round, get blunt, or become broke. The price is little more than that of the common spade.

1161—1144. *The water foot spade* (fig 1143) should be made very strong the shaft or handle should be square, with the angle rounded off, and strongly plated over where it is joined to the cross angle at top, and to the blade below. The blade is about fourteen inches across, and twelve inches deep, quite perpendicular with sharp cutting edges, and a hilt or piece of iron (a) rivetted on for the feet. For the stocking up of hedges, taking the top sods off drains and various uses where strength is wanted, this spade will be found a most powerful instrument (*Gard. Mag.* vol. vii. p 86)

1143

1143

1163—1143. *The corn rake* (fig 1143) for using after the scythe, differs from the common rake both in form and dimensions. The head (a) of the corn rake should be made of fine ash as light as possible but strong enough to bear the driving in of a number of iron teeth; and it should be at least four feet in length and furnished with iron at both ends (b b). The teeth should be seven inches in length, and four inches apart and so curved at their points that the weight of the rake may rest upon the curve, with the points of the teeth quite free of the ground when the rake is held in a working position. The points of the teeth should be thin and broad. The handle of the rake may be of light fir and it should be six feet in length. An iron (c), passing from the handle on each side to the head, will prevent the teeth

from being twisted out of its position. A short handle (*d*), like the left handle of the scythe and fastened at a convenient spot on the shank with an iron wedge, will facilitate the passage of the rain over the ground. (*Quart. Jour. Agr.*, vol. iv p. 602.)

8162. *Cottam's improved double* has two wheels which move on the axle so as to be set at any distance apart and the flippers on the tire can also be set at any distance, so that the implement is singularly complete for dibbling wheat, linseed, mangold wurtzel, &c. Figured in *Johnson's Agr. Imp.* 1848, p. 14.

*Cottam's portable scything machine* may readily be carried by two men, and any description of farm produce can be weighed by it accurately and expeditiously. Figured in *Johnson's Agr. Imp.* 1848, p. 16.

8164. *Scythe.* The reaping-hook. It is observed by the author of an excellent article on reaping with the scythe, published in the *Quart. Jour. Agr.*, vol. iv p. 356, as a remarkable circumstance in the

history of mechanical science in Britain, that the art of cutting down corn crops should be so inadequately supplied with instruments. The reaping-hook, unlike every other mechanical instrument, depends entirely for its efficacy on the physical powers and dex-

terty of the labourer. The knife and wire spade are as simple in their forms as the reaping-hook; and yet the former has been displaced by many mechanical contrivances

while the reaping-hook remains in all its primitive simplicity. Its continued use in the field is attended with immense loss of time and money; and therefore, till an efficient reaping-machine is invented, it is proposed to substitute in many cases the scythe in its stead. The scythe is used, for this purpose, in France, Switzerland, and in many parts of Aberdeenshire, and it appears to be gaining ground everywhere.

8165. *Howden's two-edged bill-hook* (*fig. 1144*). This hook is something like the letter S. It is all round sharp, and combines the powers of the carpenter's axe, the gardener's knife, the bridge's hook, the Highlander's broadsword, and the joiner's chisel. The blade is twelve inches in length, and three inches broad. The socket is eight inches long, and serves instead of a wooden handle when the instrument is used as a knife, bill hook or axe; when it is to be used as a chisel it must be placed on the end of a long handle; and will then, either by pushing or drawing, remove small branches from the stems of tall trees. The long socket is made a little oval in the direction of the two edges in order to let the operator feel where the edges are. The chief use of this instrument, however, is for dressing hedges and for that a wooden helve, or handle of about two feet in length, is best. (*John Howden April 30 1830*)

8166. *3489.* To preserve hedge-bills scythes sickles and other steel instruments from rusting wipe them quite dry, heat them sufficiently to melt common bees wax, and then rub them over with it so as to cover the whole of the steel with a thin coating. The wax, completely excluding the air, prevents any decomposition from taking place on the surface of the steel, and when the instrument is wanted for use the wax is readily removed by the application of heat. (*G. M. 1839 p. 186*)

8167. *3505.* *Graham's sliding rule* for showing the weights of fat cattle was invented by Dr. Wollaston for Lord Spencer and may be considered an essential article for every cattle dealer. (*Journ. A. S. vol. liii p. 337*)

8168. *Cottam's dynamometer* is so arranged as to obviate the continual vibration of the pointer usual in such instruments. This is effected by a cylinder filled with oil, which is furnished with a piston with small apertures in it, the rod of which is attached to the pointer. The obstruction caused by the oil to the quick passage of the piston, prevents any slight alteration in the draught from influencing the pointer; unless the increase or decrease is continuous, when it will immediately indicate the increase or draught of the machine or field, and not the draught of any temporary impediment or cessation of resistance. (*Johnson's Agr. Imp.* for 1843 p. 18)

8169. *Cobbett's dynamometer* records on a roll of paper the distance which the plough or other implement may have passed over and the weight necessary to draw it through all its variations. (See *Johnson's Agr. Imp.* for 1840, p. 67)

8170. *3508.* A seed sifter, or machine for cleaning rye grass seed, or other grass seeds is described and figured in *Trans. H. S. vol. xli p. 202*.

8171. *3535.* *Hay turning baskets*, as a substitute for those of willows, in carrying turnips to feeding cattle, are recommended by Mr. Buist in *Q. J. A. vol. xi p. 112*.

8172. *3560.* *Slight and Little's straw-cutter* (*fig. 1145*) is considered to be the most perfect machine of

this description that has hitherto been invented. In most of the other machines the oblique position of the cutters, relatively to the hay or straw which they have to pass through is found to be attended with difficulties to the workmen when replacing them after they have been taken off for sharpening. Messrs. Slight and Little have obtained the advantage of placing the knives in an oblique direction through the body of hay without occasioning the slightest difficulty when these knives are removed to be ground. This is done by slanting the cutting-box into a position, which is twisted until its centre assumes an angle of about thirty degrees. By this arrangement, the entire efficiency of the machine is retained while its construction and keeping in order are simplified, and its price is proportionately reduced. The frame is made entirely of cast iron. *a* is the feeding-trough the rollers being only partially seen. *b* is the waste or cutting-box. *c* is the cutting beam, with the cutters attached by their bolts. *d* is a lever and weight, which, through the medium of the bridge *e* keeps a constant pressure on the feeding-rollers to counteract any inequality of feeding; *f* is the fly wheel for equalizing the motion and *g* the handle to which the power is applied. The small pulley on the fly wheel shaft gives motion to the per wheel, which is mounted on the shaft of the lower feeding roller and carries also the lower feeding pulley. This last pulley works into the pulley of the upper roller and both being furnished with very long teeth, they thereby admit of a limited range of distance between the rollers according to the quantity of feed. With one of these machines, a man, assisted by a boy to feed in the hay or straw can cut

at the rate of eight sheaves per hour; and that quantity of cut hay is found to be sufficient for sixteen horses for twenty-four hours. (*Quart. Jour. Agr.* vol. iv. p. 345.)

8173.—8665. *Tapster's tub for receiving and weighing corn*, represented in figs. 1146, 1147. The tube (a) has a movable bottom (b), which, when it is desired to let the corn drop out, is raised by putting the

foot on the pedal (e) which operates on the lever (d). The valve is worked by a spindle which passes through the collar (c). The angles at the bottom of the tube are bevelled off to allow of the free egress of the corn into the sack below it. Of course the tub should be suspended high enough above the floor to allow the corn to escape and for this purpose a platform (f) ascended by steps is required, which may be either fixed or movable. Up this platform the man walks who bears the sack of corn and the mouth of the sack being previously unfastened he shoots the contents very gently and gradually into the tub. The precaution of shooting the corn into the tub gently and gradually is essentially necessary as otherwise there will not appear to be full measure. The mode of weighing may be either by Marriot's dial engine, or by a steelyard beam: the former is the most simple. This tub was invented by Mr Samuel Taylor and is used in the extensive malting establishment under his care at Stokeferry Norfolk (*Gard. Mag.* vol. viii. p. 467.)

8174.—3571. *Baird's turnip-slicer* (fig. 1148) is considered one of the best turnip-slicers in use in

Scotland. It is made, when of full size, entirely of cast iron, and consists of a standard or frame to which is attached a hopper the frame bearing a circular piece of cast iron mounted on a horizontal axle, to

which the wheel-handle is attached. This plate is cast with a thickened edge or rim, which gives it, when in motion, the effect of a flywheel. It carries two thin cutters or knives, set parallel to the face of the plate, and radiating from the centre. The thickness of the plate is regulated by the distance of the knives from the face of the plate. Each knife is preceded by three or more lance-pointed studs, which by striking the turnips in passing, prepare the slices for falling in places when they are detached from the knife, at each revolution of the plate. This process goes on so long as the hopper is replenished with turnips, their own weight being found sufficient to hold them within the stroke of the knife. When potatoes are to be sliced, the disc above described is to be removed, and another substituted, differing from the first in having the cutting studs set closer together. In the figure, A represents the hopper filled with turnips; B, the disc of cast iron that carries the cutters; C, one of the cutting knives, the opposite one being concealed by the framework; D, the lance-pointed studs; E, the wheel-handle partially seen from behind the machine; F, the framework of the machine; G G, two bars which slide into staples, and serve as handles by which it can be removed from one place to another. (*Hill's New Soc. Trans.*, vol. 2, p. 51.)

5176—5177 The *turnip-slicer* (Fig. 1149.)

1149

usual manner the great roller (a) serving to compress the prepared ridglets, and also to communicate motion to the other parts of the machine. This is effected by means of a leather belt or a pitch chain,

1150

passing over a pulley at the extremity of the roller and another of the same diameter at the extremity of the axle (b); which last, in the common machines, always carries the seed-boxes, but in this performs a double purpose. The first of these purposes is, that by means of two pulleys which are not seen in the figure, it gives motion to two other pulleys (c) of the same diameter mounted on small axles which pass through the seed-boxes, and are each mounted with three plain wooden pulleys; the middle one is about six inches diameter one inch thick at the centre, and is diminished to about half an inch thick at the edges the other two are three inches in diameter and of proportional thickness. The middle pulleys unseen, are armed with six stout wire prongs, the extremities of which describe a circle of twelve inches in diameter, while the smaller pulleys (at c) are similarly armed with five prongs, extending to seven inches in diameter. The revolution of these armed pulleys keeps the seeds in continual agitation preparatory to their being propelled from the box. The second purpose to which the axle (b) is applied is, to carry a small wooden cylinder placed immediately under each seed-box, of five inches in length and three inches in diameter, armed with four prongs or claws, extending in a radius of three inches. In the revolution of these claws they penetrate successively into the orifice of the seed-box, and perform an operation of picking or scratching out the seeds in a regular succession. The seeds are resumed into the funnels (d) and pass from thence down the tubes in the usual manner to the ground, where a rat is powered for them by the coulters. The seed-boxes are made of sheet iron, or of the plate, of an elliptical form in the mouth; the diameter being about eighteen inches and twelve inches, with a depth of twelve inches; the cross section, taken either longitudinally or transverse being also elliptical. The bottom of the box terminates in an oblong orifice of about six inches long by half an inch wide in the clear; the latter dimension being capable of extension, or diminution, by means of two plucking screws. Each box is covered with a movable lid, to prevent the seeds from being thrown out by the agitators. The funnels, with their seed tubes, are attached to the hind part of

has lately been much improved, and in Scotland is taking the place of more elaborate machines. "The advantages of this form of slicer are, 1st, the certainty of cutting turnips free of even the smallest portion of waste, a property which few of the revolving machines possess in such perfection; 2d, its cheapness, the price being only from 25s. to 30s.; 3rd, its portability being easily carried about by one person, or it may be mounted on wheels at a small additional expense. It has the disadvantages of being only capable of cutting slices and therefore not so well adapted for sheep feeding, but it is quite as expeditious as some of the revolving machines, as a man or a boy will slice 10 qwt. of turnips in ten minutes with this machine."

5176—5177 A *turnip-sowing machine* which sows two rows at a time and deposits along with the seed a regular train of bone-dust, is described in the *Quarterly Journal of Agriculture* vol. iii p. 718.

5177 A *machine for sowing carrots* was invented by 1853 by Mr. Daniel M. Naughton farmer near Irvine, in Ayrshire. Fig. 1150 exhibits the general appearance of the machine, which is similar to those in common use for sowing turnips; the essential difference lying in the apparatus adopted for discharging the carrot seeds from the seed boxes. To the lower part of the framework is attached, in the

the coulters, and are provided with an adjustment, by means of the slits and pinching screws in the collar bar (4) of the framework, enabling the operator to regulate the distance between the rows, while, by means of the slits and pinching screws (as m) he can regulate the depth of the rot for the seed-bed. The machine is convertible into a turnip drill by a very simple alteration. The seed-boxes and the claw cylinders are removed; and, in place of the latter two barrel-shaped seed-houses of the common construction are substituted upon the axle (b). It is then a complete turnip drill-machine. When, again, it is required for sowing clover, the turnip seed boxes are removed, as also the collar bar (4). The axle (b) is then mounted with five barrel-shaped seed-houses similar to, but smaller than, those for turnips. A collar bar with five permanent coulters, is placed in the slits (17) of the frame. The coulters are perforated from top to bottom for the passage of the seed, terminating in the hind part of the lower extremity. Five funnels corresponding to the seed-houses, are inserted, one into the upper orifice of each coulters and thus the machine is prepared for sowing five rows of clover seed. (*Highland Soc. Trans.* vol. x. p. 303.)

8178.—2578. *Croskill's improved turnip drill, with apparatus for sowing bands, ashes, &c.*, is considered a very efficient implement, and is much used by those who apply the manures commonly called band-dillings. The price for one row drill is 10s. and for two rows, 14s. 10s.

8179.—3661. *A press for compressing straw or most wet cattle* is employed in North America, and it will be found described in the *Quarter Jour. of Ag.* vol. III. p. 865.

8180. *A machine for compressing peat* (*Ag.* 1151) has been invented by Mr. Walter Tod, of Longhope,

near Hawick. The same machine might also be employed for compressing earth for building walls, and for other purposes. A more powerful and elaborate machine has been invented by Mr. Aligut, the Curator of the *Highland Society's Museum of Models*, and figured and described in the fourth volume of their *Transactions*; but the simple machine of Mr. Tod, we think will be more useful in countries where the fuel is peat, and in new countries, where the emigrant might think it advisable to build the walls of his houses of dry earth. This machine consists of two strong planks of wood fixed together at each end by cross bars, and mounted upon four wheels. Two pieces of wood (a, d) at the distance of two inches from one another are mortised into the plank (a, b) at the end a, and at right angles to a. Between the upright posts (a, d) there is inserted a strong beam (a, e) twelve feet long and secured with an iron bolt passing through the pieces (a, d) which have numerous holes to admit of raising and depressing the beam (a, e) at pleasure. Two boxes are then made, one of wood, and one of sheet iron fourteen inches in length, three and a half in breadth, and three and a half deep. These boxes have lids which just fit them about three inches in thickness, to allow them to sink in the boxes by the pressure. Each box is to be alternately filled with peat newly dug, the lid adjusted, and the box placed in the machine at the point f, a man stands at the end (e) of the beam (a, e), and, as each box is placed in the machine at the point f, he bends his whole strength and weight upon the end of the beam. By this means, an immense pressure is applied to the box by a single effort, and in an instant of time. Two women may fill and remove the boxes. In this way a man and three women could compress about eight cart loads of peat in a day. One man digging and a woman throwing out the peat, could keep the machine in full operation. The peats, when taken from the machine are built up like small stacks of bricks, but so open as to admit a free circulation of air. The stacks put up in this way become perfectly dry without being moved till they are taken home. If the machine just described were to be adopted for compressing earth, boxes of cast iron, full of small holes, would answer the purpose best. The pressure is so great, that the wooden boxes frequently give way though strongly made, and secured with iron at the ends; and even the one of strong sheet iron has been bent. (*Highland Soc. Trans.* vol. ix. p. 374.)

## CHAP. II.—Implements and Machines drawn by Beasts of Labour (p. 389.)

8181.—2598. *Swing ploughs on Small's principle*. Notwithstanding the numerous swing ploughs that have been brought into notice within the last seven years, the best practical agriculturists who follow the Scotch system, such as Morton and Donaldson in England, and Oliver, Professor Low, and Mr. Stephens in Scotland, seem to be of opinion that the improved Small's plough has not yet been surpassed. It would appear however from experiments reported in the *Journal of the English Agricultural Society* vols. iii. and iv. to be afterwards quoted that there are some ploughs, both with and without wheels, which are drawn through the soil with less power than the best Scotch ploughs. We do not, however, consider the result of the trials which have been made as warranting us in recommending any other swing plough in preference to Small's. The best forms of this plough according to Mr. Stephens are: the East-Lothian or Small's plough, the Lancashire or Wilkie's plough, and the Mid-Lothian or Currie plough. The best makers in Scotland are Wilkie of Uddington, near Glasgow and Clarke of Stirling. (*Stephens's Book of the Farm*, vol. i. p. 407.)

8182.—2600. *Wilde's improved or half-side plough* (*Trans. Hort. Soc.* vol. xii. p. 454.) (*Ag.* 1152) is always used by Mr. Smith of Deanston, whose fields, being thoroughly drained, have a regular uniform appearance without furrows. Each of the two mould boards in this plough is attached to the rest a, by two bands of iron, c, c by which with the end of the handle d, they are alternately raised or depressed; while the one is in a working position, the other is carried above. The rest a, extending to the coulters at f, in moving the mould board, moves also the coulters one inch at the point, so as to give it the proper position with the point of the sock at g.

8183.—2616. The *Deanton's subsoil plough* (*Ag.* 1153), as designed and used by Mr. Smith on the farm of Deanston, has been found peculiarly efficacious in rendering productive a sterile soil upon a tenuous

1153

bottom. It has been constructed so as to be of easy draught, and to penetrate to a depth of from sixteen to eighteen inches from the surface. It has no mould-board, and is intended merely to break and stir up the subsoil, without bringing it to the surface or mixing it in the first instance with the incumbent soil. It is, in fact, a horse-pot, and readily loosens and throws out all stones not exceeding seventy pounds weight. It is drawn by four horses two and two abreast, and it is held in the usual way by one man. In working, the common plough goes before it, taking a furrow ten inches by six inches, the subsoil plough following in the bottom of that furrow and going deeper by ten or twelve inches. When this plough is applied on a tedious bottom, and in conjunction with parallel drains about two feet and a half deep, and distant from twelve to twenty feet from each other it produces wonderful effects in attaining a deep and dry soil, and even on gravelly and sandy bottoms its effects are considerable, and are especially apparent in the succeeding pasture. The cost of such a plough, with a team or main

1153

chain for the leading horses to draw by, is about 5*l*. The ordinary swingle-trees and harnessing suit, with straps over the quarters of the leading horses to bear up the swingle-trees to their buttocks, and a chain from the collars of the hind horses to bear up the team chain. This plough with four horses a ploughman, and a lad to drive, will do about an acre imperial per day at a cost of about 1*l* 1*s*; no charge being made for the common plough, as the land would require a furrow at any rate. Such ploughs are made by Robertson Smith, of Drip (by Stirling) on the estate of Blair Drummond (*Highland Soc. Trans.* vol viii p. 306). On July 7th, 1843 Mr Smith gave a lecture on this plough in Walls a room, London in which he exhibited the first subsoil plough which he had made and which after twenty years use had not required the slightest alteration in the construction. A modification of the subsoil plough by Mr Peasey is known as the Charlbury subsoil plough and another was made in Stirlingshire by Mr Armstrong whose implement combines a common plough and a subsoil plough and is considered an important boon to small farmers, as facilitating among them the system of subsoil ploughing.

1154.—3087 *Wills's improved friction wheel plough for two horses.* The invention of the friction wheel plough is claimed by Mr Morton, an implement manufacturer of Leith Walk, Edinburgh, who conceived the idea of introducing a wheel into the body or bosom of the common plough, about fifteen inches in diameter to act as the sole, so far back as 1814. The average draught of the ploughs where the wheel was applied was reduced about one fifth or to about two cwt and three quarters. He manufactured a number of these ploughs both for home and foreign use but in a short time the farmers in the neighbourhood of Edinburgh left them off giving as a reason for so doing that they required more attention from the ploughmen to grease the axle of the wheel than the latter were willing to give (*Gard. Mag.* vol vi p. 355). We may notice it, as a remarkable circumstance, that Professor Low in his *Elements of Practical Agriculture* published in 1834 describes only small plough without mentioning Morton, Wills, or any other improver and without once introducing the subject of wheel ploughs of any kind. The invention of the friction wheel is also claimed by Mr E. Elliott, who lately managed a farm near Shepperton in the county of Middlesex. In the *Farmer's Journal* for August 1, 1851 an account of an experiment is given in which Wills's improved plough without a friction wheel was tried against the same implement with a friction wheel and both against the common swing plough in use in Middlesex. Wills's plough, without the friction wheel required four cwt. two quarters with a friction wheel three cwt and the common Middlesex swing plough six cwt. Notwithstanding experiments of this kind, it is an undeniable fact, that the old, heavy clumsy Middlesex plough, which it appears requires twice as much strength to draw it as Wills's friction wheel plough, is still that commonly used in the county! We cannot suppose that any class of men would persist in a practice which they knew to be decidedly opposed to their own interest, and therefore we unhesitatingly conclude that in ignorance, or prejudice, or both, we must seek for the cause of these men so obstinately adhering to the practice of their forefathers. The truth is, as we have elsewhere observed, the farmers are the only class of Englishmen who do not read.

1155.—3087 *Peasey's drawing plough* has been used extensively by Sir C. M. Barrall in clayey soil, at Knappe Castle near Merton in Devon, by which the land has been increased in value one third. The drains are made in parallel lines about 8*½* feet apart; they are from 34 inches to 36 inches deep, a file is laid in the bottom and, charging at the rate of 2*s*. a day per horse the total cost, the file being made on the spot, is about 6*s* per acre (*G. M.* 1840 p. 102).

1156.—3088 *Comparative estimate of ploughs of English agriculturists.* Scotch agriculturists, with scarcely any exceptions consider the Scotch swing plough as preferable to all others but since the establishment of the Agricultural Society of England, a number of experiments have been tried with wheel ploughs and swing ploughs of various kinds, and the general results are, that certain wheel ploughs are of easier draught than swing ploughs and that some English swing ploughs are of lighter draught than the most approved Scotch swing plough. The progress of the inquiries of the English Agricultural Society is thus summed up by Mr. Fanny in an article published in November, 1845:—“At the time of our foundation, four years back, the Scotch iron swing plough was stated to be the most perfect form of plough. Lord Spencer having remarked that, from his observation of ploughing-matches, he doubted whether swing ploughs had any advantage over those with wheels, a prize was proposed by our society for the best essay upon the subject, which was won by Mr. Hensley who applied the

brought-gauge for measuring the strain arising to the horses from different ploughs, and found that these wheel ploughs he tried inflicted the least labour upon the cattle. Following his example, I tried several ploughs in the same manner, and with the same result. It further appeared that there was a much wider difference in the draught of ploughs than had been suspected, and even that, of two ploughs used by two farmers in the same parish and on the same soil, one was heavier for three horses than the other for two. The old Berkshire plough casting the cattle a tremendous strain of 25 stones, while Hart's improved one-wheeled plough was drawn by them with an exertion of 14 stones only. One of Messrs. James's was hardly surpassed by Hart's in lightness, and it certainly made better work. The Scotch were the heaviest of the spring ploughs. The next trial was by Mr. Trueman at Liverpool, who in South Wales, who set an old Welsh plough of the country against Hart's. Here again the old plough was more severe for three horses than Hart's was for two. The old plough stood at 20 stones, Hart's at 13. The next experiments were made by Lord Tweeddale, and in these the Yester plough equalled Hart's plough in lightness. The next trial was before our judges at Liverpool, whose words I will quote from their report. It appears that in almost every case the draught of the wheel ploughs was less than that of the spring kind, and it must not be conceded that the wheel ploughs in every case actually turned over more soil than the spring, for the share and sole of the former maintained a flat, horizontal position, whereas all the spring ploughs lent more or less to the land side, cutting to a less depth on the right than on the left-hand side. Consequently the furrow bottoms left by the wheel ploughs were more even than those excavated by the spring ploughs. On this occasion, a wheel-plough by Messrs. Barrett, of Reading was the lightest, marking 25 stones; Hart's the next, 24 stones; a Scotch and a Northampton swing plough the heaviest, standing each at 40 stones. I cannot but remark how little our mechanists yet know of the draught of their ploughs when implements could be brought forward to compete for a prize at a great public meeting, some of which gave as much work nearly for four horses as others for two. The latest published record of trials is a very careful set of experiments by Mr. Hannam of Dorchester in Oxfordshire. Here again, as in Wales and in Berkshire, the lightest plough stood at 15 stones, the old Oxfordshire plough at 33 stones, the Scotch swing plough at 50 stones. The lightest plough in this instance was Messrs. Barrett's. There only remains the interesting report of our judges on the ploughs which competed at our Bristol meeting. There, again it will be seen that the lightest plough was a wheeled one, Mr. Howard's of Bedford, which stood at 22, the heaviest a Scotch swing plough which marked 44, the next heaviest, another Scotch swing plough which marked 46, and in the words of our judges, it is worthy of note that the resistance of Mr. Howard's two-wheeled was less by 4 stones than that of his swing plough. From these repeated trials, which have arisen out of Lord Spencer's remark, we may now come to the conclusion that wheel ploughs as he suspected are superior to swing ploughs, in ease for the cattle and are also superior in the work they perform, that the Scotch swing plough in particular is very severe for the cattle, that since in three country trials the draught of the ploughs was found to differ as two to three—that is, as two horses to three—more attention is required on the part of our ploughwrights to the easiness of their draught, and lastly that since in our two public competitions at Liverpool and again at Bristol the draught of some competing ploughs doubled that of the winning plough, it appears very clearly that our ploughmakers as a body are not thoroughly acquainted with the qualities of their own implements, otherwise the race could not be so unequal. (*Journal of A. S. vol. li p. 187*)

8187 *Comparative estimates of ploughs by Scotch agriculturists.* Notwithstanding the experiments made in England under the auspices of the Agricultural Society seem to prove the superiority of wheel ploughs in many instances, yet the prejudice in favour of swing ploughs seems to remain unabated in Scotland. Mr. Bight in Stephens's *Book of the Farm* observes writing in 1843, no ploughman who has been able to wield the swing plough will ever suffer himself to be accommodated with the addition of a wheel to his plough (for he will always consider wheels an inconvenience) and this he does not from a conviction that wheels increase the labour of his horses, but because to himself they appear a source of annoyance, and here it may be further remarked, as regards wheel ploughs, that, since the wheels must always have a tendency to increase the draught, and on that account are objectionable so also, if a plough can be wielded with equal and perhaps better effect without wheels than with them, the excuse that a wheel plough may be wielded by a man of inferior qualifications is of small value. Any man so trained to handle a plough though every man will not be equally successful, and since in the whole of Scotland not a wheel plough is to be found, except as a curiosity while her ploughing is at least not inferior to that of any part of the kingdom and as the chances are surely equal that the ploughmen are not all equally good it is evident that ploughing can be satisfactorily performed without wheels. If ploughing can thus be performed over one part of the kingdom with an implement of the simplest form and in a satisfactory and economical manner there can be no necessity for using a more complicated, and more expensive machine to perform the same work in another part of the kingdom, where it is at least not better done or done at less expense. (*Stephens's Book of the Farm, vol. i p. 645*)

8188—3664 *The Uley Cultivator.* One manufactured at Lord Ducie's iron works at Uley in Gloucestershire, and known as Lord Ducie's, or the Uley cultivator, is recommended as the best, and, from the description, it appears to be an admirable implement and by far the best of its kind which has yet appeared. It has been tried for paring as well as stirring, and is found to move the whole surface of the ground most perfectly. The implement is altogether about 6 cwt. in weight. It is supplied at Uley at prices varying according to the size, weight, &c. at which it is ordered certain forms of the implement being intended for two horses and others for four. According to the *Times* the iron work is chiefly cast, the weight about 10 cwt. and the price 15*l*.

8190 *Stewart's horse-drawn for harrow and throwing turnips.* (*Fig. 1165*) The form of this implement of this kind occurred so long ago as 1776 to Mr. Stirling of Strathclyde in Fifehire, one of the Scottish

1184

1186

martyrs, but we are not aware that it was ever before realized. A set of revolving blades in this has work across the rows of crops, leaving the plants at regular distances. (*Johnson's Agr. Rep.* for 1843, p. 57.)

8191.—3000. *Crosskill's broadest manure sower* (fig. 1186) which is drawn by one horse, will contain 8 bushels of manure in a state of powder. It is 6 feet wide, and can be regulated so as to deposit the manure at any given rate per acre. By placing the drill box in a vertical position the quantity of manure sown is increased, and the contrary by placing it in a horizontal position. Price 12*l.* 1*8s.*

8192. *Cotman's improved serrated chain harrow* (fig. 1187) consists of a number of serrated iron discs interwoven and linked

together with iron rods, the whole forming a surface of thirty superficial feet, interspersed with nearly four hundred points or discs. It is said that no clod can escape the influence of this harrow, and that it will be found particularly serviceable in harrowing after seed has been sown. (*See Johnson's Agr. Rep.* for 1843, p. 17.)

1187

8193.—2703. *Crosskill's clod-crusher roller* (fig. 1188) is intended to effect the same objects as the *stony roller*. It consists of a number of segments fixed on an iron axle six feet six inches long. Ploughed land once rolled by this machine is said to be reduced to a finer state than by two or three rollings and harrowings with the ordinary machines. It is drawn by three horses, and cleans itself, even when load

1188

is in the very toughest state. A number of these machines have been manufactured by the inventor at *Beccles*, and used by the farmers of the surrounding country. The price of a machine, including two iron road wheels to attach to it when not in use, is from 17*l.* to 19*l.* delivered in *Hull*. Mr. Crosskill

informs us (June 12, 1853) that the demand for this machine is from 100 to 200 annually. For the first two or three years after he invented it, he did not make above 5 or 6 annually.

8104.—8711 *Crowell's liquid manure cart* (Fig. 1159.) *Is made about 200 gallons. The body is made of cast iron there is a brass valve lever, &c. by which the liquid can be let out by the iron spout & which the spreading hose &c. and a pump. From pump & which cannot easily choke or get out of order with a flexible leather pipe &c. 7 feet long, with a 3 feet copper pipe at the end for drawing up the liquid from the manure tank. Altogether this seems an excellent machine. The price delivered in Holt is 74. Dean's liquid manure cart figured in Johnson's *Agr. Imp.* p. 22 appears also to be a very excellent machine cost, complete 244.*

1159

8105.—8711 *A sheep and weight under-cart* is thus described by Mr. Donaldson in the *Farmer's Magazine* vol. viii. p. 81. — A barrel, holding 100 to 200 gallons, is placed on a pair of wheels and shafts in the usual way. A pump, three inches in diameter is placed close by the side of the barrel, of indefinite length, with a rose copper end, and in the pipe small copper or tin rings are placed two inches distant, to prevent the external air from pressing together the sides of the pipe and thus excluding the water. The cart being placed on the bank of a river, brook, or pond and the pipe thrown into the water with the rose end immersed a man will pump 150 gallons in ten minutes without the trouble of having a road into the bottom of the river and with the great advantage of the horse standing dry and not plunged into three feet of cold water on a winter day in the usual way of filling by leads and standish. A stop-cock is fixed behind for discharging the water. When the cart is travelling the leather pipe has over the barrel, fastened by two iron catches. The barrel being filled, and driven to the place required, the leather pipe is immersed in the barrel by a hole in the top sufficient to admit the rose end. A small iron rod screws down by the side of the piston rod, upon the upper valve, and shuts in fast. A relief main with a check valve, is opened between the two buckets in the pump, upon which is screwed fast a leather pipe with a copper tube on the rod. One man directing this pipe, and another pumping, converts the cart into a sort of fire engine that may be very useful in cases of emergency, throwing the water forty feet horizontally and over any house of two stories. Any hayrack or corn rack, it is also very useful for garden walls and fruit trees. By increasing the size of the barrel and by applying more power a very sufficient engine may be made and answering other purposes at the same time.

8106.—3781 *Munn's reaping machine* was invented in 1830, but neglected till 1836, when it was improved, and in 1838 it was exhibited at an agricultural meeting at Kelso. It differs from Bell's reaping machine in being drawn instead of being pushed and in depositing the corn in a continuous swath nearly at right angles with the line of direction and on the side opposite to the standing corn. Both these are advantages which we hope will not be lost sight of by the mechanist who may at some future time make such a reaping machine as shall come into general use. An engraving with descriptive details of Munn's reaping machine will be found in the *Quarterly Jour. Agr.* vol. iv. p. 260.

8107.—3785 *Crowell's improved Scotch cart* is made entirely of iron and is peculiarly adapted for hot climates, with narrow iron wheels, having the tire  $2\frac{1}{2}$  in. wide, by  $\frac{1}{4}$  in. deep the cost is only 124. The cart made of wood, in the usual manner costs 104 10s.

8108.—3786 *An improved corn and hay cart* is exhibited in Fig. 1160 and is in general use in the neighbourhood of Alloa. The advantages are, "great simplicity of structure and what constitutes its chief excellence, the load takes its full breadth at the very commencement, by which the centre of gravity of the load is brought lower than in either the common corn-cart, or the dung-cart with top-frame, whereby a greater degree of stability and safety against the risk of upsetting is acquired, and a greater facility of loading. Another advantage may be pointed out, in the case with which it is converted into a cart for the conveyance of timber by simply unbolting the frame from the shafts, and in its place laying two single cross bars, one before, and another behind the wheels." (*Trans. H. S.* vol. xi. p. 395.)

1160

8109.—3773 *The construction of threshing machines is everywhere very superior, even in Scotland, where they were first invented and where machines of the largest power impelled by water or steam are erected at great expense. The editor of the Quarterly Journal of Agriculture has the following judicious observations on this subject. — "Were threshing machines constructed on correct and unerring principles like the machinery of a timepiece or of a steam-engine, or even of a flour-mill, the advantage to the farmer would not only appear in the shape of cleaner threshed straw and of economy of time and labour, but the millwright himself would derive great advantage in the certain possession of materials which would enable him to erect threshing machines that would suit the particular localities in which they were to be placed. There is no way of arriving at this perfection but by the institution of experiments to ascertain what may be the simplest construction of the threshing machine, and the best mode of applying the least quantity of moving power to execute the desired work satisfactorily. These desiderata would produce the advantage of threshing the corn at the least cost. Threshing machines are of so durable a nature that they are not often renewed, but for that very reason they should be constructed in the best manner at first. A set of patterns could be made from the results of these experiments, and sent out to those makers in the country who could grant security that they would only erect machines which were conformable to these patterns. In the course of time the country would be stored with efficient and easily moved threshing machines. The ill-judged desire of the farmer to have a machine that will not cost much money often leads the millwright to adopt expedients in its construction which he is conscious are not suited to work well together. This is one reason among many others, to prove the propriety of landlords erecting threshing machines at their own expense, upon their farm-standings, and of giving the tenants the use of the mills as well as the standings, and of obliging them to keep the machines in repair as in the case of the buildings." (*Quarterly Jour. Agr.* vol. iii. p. 384.)*

8110. *The threshing machine of Wymshurst* the cost of Mr. William Williams Wynn, Bart. is considered one of the most complete in Britain. It was erected by the late Mr. John Gladstone, of Castle Douglas, Kirkcubrightshire, about the year 1813. This machine separates the corn from the straw and delivers both straw and corn into their proper places without the assistance of manual labour with the exception of feeding. The site of the mill is on a declivity, and the barn has three floors or stages; the upper most of which opens into the stack yard, making it very convenient for carrying in the sheaves, and second one contains the first winnowing machine, with a chaff-house, partitioned off under the eaves, and

descending to the floor below, with a door into the straw-house, and one into the outside-yard. When the corn is only to be passed through the first winnowing machine, the corn elevators and second machine are thrown out of gear, and the corn delivered on the second floor where the bruising machine is fixed. The under floor contains the second winnowing machine with the lower end of the corn elevators. If necessary the clean corn may be delivered on this floor instead of into the elevator trough, the ends of both machines are inserted in the shaft-chamber. The corn is put between two grooved rollers, when the grain is beaten out of the ear by four beaters fixed on the threshing cylinder, and thrown into the rake or first shaker, when it falls through the spaced bottom into the winnowing machine hopper, while

the straw is raked forward and thrown upon the travelling shaker where it is thoroughly shaken, and conveyed into the straw-house. The corn passes through the first winnowing machine when it is cleared of its chaff, short straw &c. the latter is thrown into a set of elevators which carries them up to the feeding-table, to be threshed over a table with the unthreshed corn. This is a very useful appendage to a threshing-mill, it takes all the refuse from the faners, which generally accumulates about a barn floor (or is carried up by hand) whereas the elevators carry all away and thereby leave a clean barn. The corn passes through another pair of faners, and from thence into the corn elevator trough and is carried from thence into the granary and thrown into the weighing machine, which is connected with an index in the barn and the partition walls facing the man at the feeding table which shows the quantity threshed very nearly. The machine occupies part of three floors. The water wheel is in a house beside the barn and in a room above the wheel is a Scotch barley-mill, and beyond it is a very complete saw-mill both driven from the same wheel, which can be detached when the threshing part is at work, and

the threshing part, when the saw or barley mills are wanted. In the middle floor is an oat crusher driven from the upright shaft. It can be put out of gear if wanted.

893. Description. In Apr. 1161 1162, 1163. *a* is the water wheel, eighteen feet in diameter by four feet wide; *b* a pit wheel, eight feet in diameter which works into a pinion *c*, of fifteen inches in diameter fixed on the upright shaft; *d*, a bevel wheel five feet in diameter which turns the drum pinion *e* of nine inches in diameter; *f* the drum or threshing cylinder three feet four inches in diameter outside of the beaters, and four feet and a half long, with four beaters turning upwards with a velocity of 300 revolutions per minute; *g*, a bevel wheel, twenty-one inches in diameter turning a pinion of five inches and a quarter diameter on the axle of which is another pinion five inches in diameter working in the face wheel *h* with two rows of teeth, one of thirty and the other twenty-four teeth; this pinion slides along its axle into either set of teeth; for instance, into the one of the smallest number if the straw is long and into the other if it is short, loose, and irregular. The rollers are about three inches and a half in diameter. The wheels *g* and *h* are each twenty-one inches in diameter, working into the pinions *d* & *a*, five inches and a quarter in diameter which give motion to the rake or first shaker at the rate of forty-five turns per minute; *k* is four feet in diameter to the extremity of the teeth; *l*, two wheels each twenty-one inches in diameter with pinions, *m* & *n*, five inches and a quarter each, which drive the travelling shaker that receives the straw from the rake, and conveys it into the straw-house. This shaker is composed of two endless pitch chains, worked by two steel wheels ten inches in diameter with eight studs on each on the same shaft as the wheels *m* and *n*, revolving at forty-five times per minute. These chains are kept stretched by two smooth wheels at the further end in the straw-house; between the chains are fixed round wooden rods about two inches apart. *o* is a wheel with large teeth on its circumference, which, as it turns round, depresses the point of the lever *e* and raises the end *p*. The lever is fixed on an axle which passes through to the other side of the shaker with a short lever fixed on it to correspond with the lever *p*; on these levers, *p* & *p*, rests a small shaft on which is fixed on each end, under the plates a small drum four inches in diameter which supports the shaker in the middle, as the wheel *o* moves round. The point of the lever, *e* strikes from tooth to tooth, and thereby keeps the small shaft at *p*, in motion up and down which shakes the loose corn out of the straw which is drawn back by the under running rod into the winnowing machine hopper; *r* is the first winnowing machine; *s* the second winnowing machine; both driven by a small water-wheel, six feet in diameter, and four feet wide; the water from the large wheels supplies this one. The motion of the machine requires to be uniform, which cannot be the case if connected with the threshing part. It answers better to have a separate wheel for

the machines. The clean corn passes into the elevators *e*, from whence it is carried up into the granary, and delivered into the weighing machine *g*, by small elevators made of sheet iron, with wooden buckets and bottoms fixed to a pitch chain revolving round a studded wheel ten inches in diameter and with eight studs at the upper end, and a small wooden roller at the bottom at eleven turns per minute.

The corn is delivered into the weighing-machine box, *f*, and accumulates until there is the weight of a measure, when the box turns on its axle, and the corn is emptied into the spout which conveys it into whatever bin it may be wanted in. At the same time the part *g* turns up, and is filled as the other and, when full, descends as the other, and so on, while the threshing is going forward: *h* is a weight which slides up and down a rod fixed at right angles from the bottom of the weighing machine: if the corn is heavy, slide this up until it will balance a bushel of corn similar to what it is to be threshed; if light, slide it downwards. From the axle of this box, a small rod proceeds to two small wheels behind the index, *a*, which turns two fingers that revolve round the face of this index; it is figured from 1 to 10. For every movement the weighing bucket makes, the longest finger moves over the space of one, and for every ten, the other finger moves one. At the end of the threshing, this finger will denote pretty accurately the quantity threshed: for instance, were the long finger at *a*, and the short one at *b*, there would be nearly five bushels of corn in the bin; *x x x* are pointers five inches and a quarter in diameter each working in wheels (*y y y*) twenty-one inches in diameter each, which give motion to the corn elevators, and likewise to the tail elevators by a pitch chain revolving round the stud-wheel *w w*, giving motion to the shaft of the elevators at eleven turns per minute. The buckets are made of thin boards fixed on two pitch chains turned by two stud wheels ten inches

in diameter at the upper end, and a wooden roller at the lower (*J. Gladstone, Lamb-rook, Chester Oct. 28 1804*).  
 8202. Mr. J. Gladstone, chief engineer Chester, to whom we are indebted for the foregoing plans and description, with reference to the improved form of the threshing machine, says, "I have always understood that it was to my father we are indebted for it in its improved state.

1163

In 1788, Mr. Andrew Meikle produced the first machine of the kind, for which he took out a patent. (*See Repository of Arts, vol. x No 68.*) This was simply a threshing cylinder with the beater turning downwards, throwing straw and corn into a moving screen which separated them in a very imperfect manner; so much so, that I have heard the machines were given up, or going into disuse simply on account of the beaters striking downwards if the ears escaped the beaters immediately on passing through the rollers, they were bent under and laid close to the interior of the cylinder case, and thereby evaded the stroke of the beater. In 1788, my father made his first machine, similar to that of Mr Meikle, with this difference, that the threshing cylinder turned upwards, and as the corn came through the roller it lay upon the cylinder and, being exposed to the stroke of each beater none escaped being threshed. (*See The Repository of Arts and bright Agricultural Report of 1810.*)

8203. The late Mr Gladstone, of Castle Dow, has added the shaker to the threshing machine in 1794 and what he called a fitterer for breaking off the awns of barley soon afterwards. In 1796, he made a threshing machine, to be driven by windmill sails. In 1798, he invented the draught chains used in threshing machines, to

equalize the pressure of the draught on the horse's shoulder. In 1804, he added a travelling shaker to the threshing machine, and soon after a contrivance for conveying the corn from the fanners into the granary and weighing it at the same time. By another piece of machinery the corn may be accurately measured. "On reviewing the whole," the writer in the *Reports of the Society of Arts*, *country Agricultural Society for 1810* observes, "it is impossible not to perceive how vastly superior the machines of Mr Gladstone are to those first contrived by Mr Meikle, and what distinguished services he has thus rendered to the interests of agriculture. The machine is now competent to the threshing not only of one, but of every species of grain. It is adapted of itself to separate the straw from the corn, and convey it perfectly shaken into the straw house to clean the corn effectually to weigh and measure it accurately and to lodge it securely in the granary. If driven by water the adoption of the chain bucket enter wheel saves an inner one formerly deemed indispensably necessary and simplifies the machinery; if by horses, the person feeding it can manage without a driver from within, and assign to each horse an equal share of the draught, or such a proportion of it as may be supposed adequate to his strength. Much diminution in the expense as well as much improvement in the mode, of farm management has thus taken place. What was the work of several months, can be performed more perfectly and with more ease, in as many weeks; and the labour of the winter season can now be devoted to more valuable purposes, to the collecting and sowing of manure, and the better preparation of the land for the reception of the seed."

8204. One of the most complete threshing machines in England has been erected at the Duke of Gloucester's farm at Hagshot Park; for the following description and drawings of which we are indebted to Mr Anderson, an experienced agricultural engineer. This machine threshes the corn, husks barley, winnows, also, and cleans wire, grinds it into flour and the straw into chaff, and grinds bones for manure and any one of these operations can be performed without the other. The different parts of this apparatus are chiefly taken from machines already in existence, but some also are original. It may be mentioned as a singular and melancholy sign of the times, that the parties who have the chief work are afraid of giving their names to the public. The agriculturists of a future, and we trust, no distant day will hardly believe it possible that the destruction of threshing machines should have been popular in England in 1820. It is worthy of notice as an argument in favour of the diffusion of knowledge among the labouring classes, first, so far from threshing machines being destroyed in Scotland, they are so much in repute among the labourers of that country that a farmer who is without

one is obliged to pay higher wages to his servants. This fact is well authenticated by a correspondent in the *Essex* newspaper of February 17, 1891. (See the examination of Joseph Forster in No. 1. of *The Working Man's Companion*, and also in *Mech. Mag.*, vol. xiv p. 388.)  
The mechanical part of the machinery was executed and erected chiefly by Mr George Miller now residing near Bagshot. Fig 1164 is partly a section, and partly a side view. Fig 1165 is partly a cross

1164

section, and partly an end view; and Fig 1166 is partly a vertical section, and partly a vertical profile. The same letters are applied to the same parts in all the figures.

6805 *Description of the machinery.* (Figs 1164 1165 1166) *a* is an overhead water wheel 15 feet diameter which makes from six to eight revolutions per minute according to the supply of water on the arms of the water wheel is fixed a bevel wheel *b* of 128 cogs (seven feet four inches diameter) working into the pinion *c*, of 28 cogs (twenty inches diameter) on the upright shaft *d*; these wheels are below the ground floor and entirely hid from the view.

On the shaft *d* are two driving wheels, *e* and *f*. *e* is a spur wheel of 110 cogs (six feet two inches diameter), driving the pinion *g* of 23 cogs (fourteen inches diameter) on the shaft *h*, which leads to the floor above, and turns the upper millstone; *f* is a mitre wheel of 40 cogs (two feet diameter) working into two wheels, *i* and *j*, of the same dimensions.

On the same shaft as the mitre wheel, *k* is a spur wheel, *l* of 300 cogs (six feet eight inches diameter), working into the threshing machine drum pinion, *m*, of 30 cogs (eleven inches diameter). The spur wheel, *l*, also drives a wheel, *n* of 30 cogs (twenty-two inches diameter), on the same axis of which is a small wheel, *o* of 36 cogs (ten inches diameter) working into the wheel *p*, of 131 cogs (three feet four inches diameter), on the axis of the first rake or shaker; the wheel *p* gives motion to the intermediate wheel *q* of 75 cogs (two feet diameter), which works into the second shaker wheel of the same dimensions as the first shaker wheel *p*.

On the spindle on which the wheel *n* is mounted is a small shifting pinion, *r*, of 17 cogs (seven inches diameter), working into the faced wheel *s* on which are two rows of cogs, one of 30 and the other of 36 cogs each. On the same axis as the faced wheel *s* is a bevel wheel, *t*, of 30 cogs (eight inches diameter),

working into the wheels *u*, and *v* of 40 cogs (eleven inches diameter), on the lower feeding roller spindle; these two wheels are not fixed on the spindle, but revolve freely on turned parts of the shaft, and give motion to it by means of the clutch and handle, *co*. When the machine is at work the clutch is in the wheel *u*, giving to the feeding rollers the required motion; should it be necessary to stop the rollers, the handle *co* is moved from the feeding board, and the clutch disengaged from the wheel *u*. Should the handle be moved further from the feeding board, the clutch is thrown into the wheel *v*, and the rollers turn the reverse way.

1165

8906 The conveying machine under the shakers is driven by a sheave on the drum axle, and a rope leading to a sheave on the former spindle; to dress the grain thoroughly it is conveyed from this machine, and passes through two winnowing machines one placed above the other; this is effected by means of a canvas cloth, on which are strips of wood half an inch in thickness; the cloth revolves on two rollers, and is set in motion by a rope leading from a sheave on the shaft *f* to a sheave on the upper roller spindle.

As it is absolutely necessary to have a steady and uniform motion to produce the best possible sample from a winnowing machine, and as the velocity of the threshing machine is subject to vary, from irregular feeding and other causes, the winnowing or dressing machines are set in motion by a small water-wheel, *a*, five feet diameter, on the axle of which is a bevel wheel, twenty inches in diameter working into a pinion on an inclined shaft, *g*. On the upper end of the shaft *g* is a bevel wheel working into a pinion, on the axle of which is another bevel wheel giving motion to the shaft *a*, which turns the runners by means of small mitre wheels.

8907 The long-roll and chaff-cutting machine are driven by the mitre wheels *f* and *h*. On the shaft *z* is a shanking pinion, *i*, of sixteen cogs (ten inches diameter), working into the wheel *4* of 40 cogs (two feet four inches diameter), on the axle of which is a pinion, *k*, of 16 cogs (ten inches diameter) driving the wheel *6*, of 40 cogs (two feet four inches diameter), in the axle of one of the lower crushers the

upper pair of crushers are driven by the wheel 6, working into a wheel, 7 in the upper crush or spindle. The crushing rollers are set to or from each other as the nature of the work may require. When the bones are large, the upper pair of crushers only are used in passing the bones the first time through, an inclined board being placed to prevent them from falling into the lower set; this board is removed at the second time of grinding, and the bones pass through the two sets and fall into the revolving circular screen 16; any bones that will not pass through the mesh of the screen are again put into the mill. The screen is set in motion by the wheel 6, working into a pinion not shown in the drawing and by a shaft and universal joint connecting with the axle of the screen.

On the shaft 2 is a bevel wheel, 8, of 46 cogs (twenty-one inches diameter), driving the pinion 9, of 16 cogs (nine inches diameter), on an inclined shaft leading to the floor above; on the upper end of this shaft is a bevel wheel, 10, of 48 cogs (twenty inches diameter), driving a pinion, 11 of 17 cogs (nine inches diameter), on the spindle of the chaff-cutting machine.

When the threshing machine only is at work, the mitre wheel 12 is thrown out of gear by the lifting screw 13; the pinion on the flour mill spindle is raised above the spur wheel 14 by the screw 15.

When the threshing machine is not at work, the mitre wheel 12 is thrown out of gear by the lifting screw 14.

1169 A portable hand corn mill with French burr stones capable of being worked by one man, is shown in Fig. 1169. The cost of this machine is 10*l*., but there are various others adapted for being worked by two men, or by horse or engine power at various prices, from 10*l* to 20*l*. When made entirely of iron they are comparatively of little use. The manufacturer of these machines is chiefly Dean of Birmingham (Johnson & Agr. Jany for 1843, p. 33.)

8210 *Brick and tile making machines* have recently been invented by various persons. One by the Marquis of Tweeddale is in most general use, and he has recently invented a hand drain-tile making machine which was honoured with a premium in 1843. Messrs. Ransome have also brought forward a new machine for making tiles and bricks, which received a silver medal at the meeting of the English Agricultural Society at Derby in 1843.

8211—8217 A *horley hummelling machine* of a simple but very efficient construction, is described in *Trans. H. S.*, vol. x. p. 284. "The machine consists of a deal box (Fig. 1170) in the form of a truncated square pyramid 30 inches on the side at the base, 20 inches at the smaller end and 45 inches in length. In the interior of the box the two inner angles are filled up with wood so as to form the half of an interior conical surface; while the two upper angles are left void, except that their surface is thickly studded with iron spikes, driven into the wood of the box. An iron axle, or shaft, *a*, *b*, as seen in the longitudinal section (Fig. 1170.) passes through it, in the line of the axis of the conical surface, and is supported on bearings at each end, formed in the bars crossing the ends of the box. The shaft is armed with two rows of blunt iron beaters, seven in each row all lying in one plane; the beaters on the one side of the shaft being placed alternate with those of the other.

The pulley *g* giving motion to the beaters, is driven by a strap from the fan-shaft, or from such other motion as may be found convenient, giving the beaters a velocity of about 400 revolutions per minute.

"The grain received from the spout of the hummers is violently agitated in its progress among the revolving beaters, and the lower side of the case having a considerable inclination, the grain is advanced during the process towards the lower orifice through which it is ultimately discharged; that opening is made capable of regulation by means of the slider *h* which serves, at the same time, to retain the grain within the box until it is divested of the awn, and prevents also its being scattered about by the agitation of the beaters. The hummer having no permanent fixture, it can be removed with great facility when a change of grain comes to be thrashed.

Hummelling machines, on this principle are certified to have been constructed in different situations, and to have given decided satisfaction. (*Trans. H. S.*, vol. x. p. 285.)

8218—8220 *Applications of steam to purposes of husbandry* showing the saving in horse corn that might be made by employing locomotive engines instead of horses. (*Quarter Jour. Agr.*, vol. v. p. 84. and p. 478; vol. vi. p. 411; and vol. vii. p. 325.)

### CHAP. III.—Edifices used in Agriculture. (p. 442.)

8221—8211 *Edifices to use in agriculture* In the *Encyclopædia of Cottage Farm, and Rural Architecture* we have gone into this subject in greater detail than could wish propriety have been done in a

work entailing so extended a view of agriculture as the present volume. In that work, including the Supplement to it published in 1845, we have not only given a great variety of the very best plans for barns, or farm-houses, which have been executed in Britain within these few years; but we have given detailed plans, sections, and specifications of all the component buildings of a farm yard, and of their sitings as, barns, and outbuildings.

6214.—1818. *Stables as Sweden have the floors laid with perforated planks, so that no wet will lodge on them, and no litter is allowed. The same thing was practised in Harley's dairy. The Swedes attribute the soundness of their horses' feet to their stable floors.* (*Brit. K. M., N. 2., vol. iv. p. 405.*)

6215.—1820. *Doors, which are likely to meet with obstructions on opening towards, or sometimes becoming obstructions to things passing outwards should be mounted on crooks and bands, so as to open and close back against the wall, or what is better, into a recess in it protected by a flange. The door may be held in its place in the recess by a bolt.* (*Book of the Farm, vol. i. p. 115.*)

6216.—1827. *Doors, to be proof against the access of rats from beneath should be formed of wood, or covered over with asphaltum, which is found to be proof against every kind of vermin, and also to bear the action of the alkali. The slaps upon which the door is laid, should rest upon stones and lime building, raised two feet from the ground, close to the turn wall, and the mortar and stones must be pushed close to the upper edge of the slaps, up to the heels of the floor. According to the width of the barn, the slaps should rest also upon one or two supports of stones, so hewn as to permit an footing to any vermin; and which will support the middle of the floor. By this contrivance, the space from the floor to the ground is made too deep to permit any small animal, standing on its hind legs and gnawing the floor, while dogs or cats can easily pass under it.* (*Quarter Jour. Agr. vol. iii. p. 328.*)

6217.—1828. *Hay-horns are little used in Scotland, notwithstanding the moisture of the climate compared with that of England. In making meadow or natural hay they have lately been found of great advantage in Scotland, where meadow hay of the same degree of dryness that would rot if put into a rick, will keep perfectly if put in a hay shed. This arises probably from an increased evaporating surface, and the hay being put in loosely. Were landrads sufficiently alive to the value of the hay barn, one would be built on every standing in districts where meadow hay is made.* (*Trans. R. S. vol. xiv. p. 597.*)

6218.—1826. *Labourer's cottages.* Having entered on this subject at length in our *Encyclopædia of Cottage, Farm, and Villa Architecture*, and there given numerous plans accompanied by descriptions, specifications, estimates, and critical remarks, we shall not here repeat any thing which has appeared in that work. In the progress of the improvement of the dwellings of country labourers in what we have termed at heart, next to the education of their offspring we cannot let pass this opportunity without contributing something further to the subject. We shall therefore give one article, entitled the *Acme ideal of an English labourer's cottage*, by a most benevolent and enlightened clergyman, who adopts the signature of Selim; and another on building cottages with mud walls, by a professional man, Mr. Wilds of Hartford. This gentleman, having been in North America, is deeply impressed with the importance of this kind of knowledge to emigrants, who, at present, too frequently build their houses of wood, and consequently sooner or later suffer from accidents by fire, or what is almost as bad, live in continual fear of doing so. To these we shall add the design of a stone-walled agricultural labourer's cottage recently built, along with a number of others of the same kind, on the estate of William Laurence, Esq., in Gloucestershire.

6219. *The Acme ideal of an English labourer's cottage.* The leading feature in the exterior of a labourer's cottage should be a picturesque simplicity which is a sort of medium between superfluous decoration and unmeaning plainness. This appears to be the only character of which a cottage is susceptible; for as plainness is uninteresting so it offends our sense of propriety to see a building of this description bedecked with costly fantastic ornaments, which are evidently unsuited to the simple unrefined habits of human life. But a picturesque simplicity is seldom the prevailing character of modern ornamental cottages. They are often decorated with towers and battlements in the castellated style of Gothic, or in the romantic style, with elaborate painted windows, crosses, and pinnacles. May instances have occurred where the two styles have been united in the ornaments of a cottage dwelling. It cannot be denied, that a picturesque effect is produced by this mode of embellishment. All I contend for is, that such ornaments are altogether unsuited to a dwelling of the lowest order. Should it be objected, that, if we reject this mode of decoration, we must have recourse to ruin and decay to produce a picturesque effect, I answer that as much of this effect as we may require may be produced. I think, by irregularity of form and outline, and irregularity, in fact, the only effect aimed at by the use of Gothic ornaments. But as my object would be only a picturesque simplicity I should discard useless and inconvenient irregularity. In so small a building as a cottage a slight irregularity would be sufficient to give it a picturesque character, and the simplest embellishments would give it an ornamental effect. And thus, I conceive, is all we require to produce what I understand by picturesque simplicity. Though I am an advocate for simplicity, however, in cottage architecture I would in some measure sacrifice even simplicity to the picturesque because the beauty of a neighbourhood frequently depends upon the style of the labourer's dwellings. These are the prevailing buildings in all rural scenery. They are occasionally so placed and associated with surrounding objects, that they present the most striking features in the landscape; and the effect of particular scenes is not unfrequently produced by the form and situations of the cottages. Hence a picturesque exterior is one of the chief requisites in an ornamental cottage; but it should be a simple pleasing style of picturesque which does not interfere with internal comfort and convenience; produced by slight irregularity of form, and by unobtrusive and appropriate ornaments. I am not at all disposed to sacrifice internal comfort to outward effect. I think a picturesque exterior may always be united with a comfortable interior; and I now proceed to give the description of a cottage in which I shall endeavour to exemplify the union above alluded to.

6220. *Site of the cottage.* As the comfort of the inmates and the general effect of a building depend materially on its site, the situation of a cottage is the first thing connected with it that requires consideration. A general rule for the situation of a cottage is, that it should be properly supplied with water; be dry airy and sheltered and admit of a sufficient allotment of garden ground adjoining the house. And I am an advocate for rather a scattered village, because among other advantages, it affords an opportunity of erecting the cottages in proper situations. A damp situation is the principal thing to be avoided. It is a nuisance in all cases; but especially to a labouring man, who cannot afford to spend any thing in draining, or much in fuel, whose health is his only source of wealth, and to whom it is necessary both for health and comfort, that he should have a dry house to come to, after long exposure and severe exertion in the open air. Besides being dry the site of a cottage should be airy and sheltered. Every dwelling should have a proper circulation of air around it, or it cannot be dry; and a cottage should be sheltered, that it may be warmed with less expense of fuel. The shelter should be so placed, however, as not to interfere with a full exposure to the sun. We will, therefore, suppose our cottage placed on a gentle eminence in the neighbourhood of other dwellings; and sheltered, in part, by higher ground at a distance, by a wood, or by groups of trees, and in part by its own orchard and outbuildings, some of these so placed as to appear above the roof, but leaving it fully open to the south. The situation would be more desirable if a stream of water happened to run near, or if it adjoined a meadow, or a public road; and it would possess the advantages of dryness, shelter and cheerfulness, besides others which are of consequence to the general effect of the building to be erected upon it.

6221. *Style of the cottage.* Having fixed upon the site of the cottage the next thing to be considered is, in what style the building is to be erected; for even a cottage, I think should present some appearance of architectural style. I have already contended that the Gothic is inappropriate to a dwelling of

this description, and a building in the Grecian or Roman style, upon an small scale as a cottage, must be plain and formal, and deficient in picturesque effect, unless it be an elegant and costly edifice. There remains, therefore, only what is called the old English style, which is, I think, the proper style of architecture for an ornamental cottage. It admits of great irregularity and variety of form, and is suited to houses of all dimensions. Its ornaments may be adapted to the small-est dwellings; the irregularity it allows in the exterior may be made conducive to internal convenience; and it has this peculiar advantage, that we have many beautiful models of old English cottages in all parts of the kingdom. It has, also, this additional recommendation, that it is not an expensive style, and may be executed in almost any kind of material. A cottage in this manner may be built of stone, brick, flint and chert, or even of wood and plaster; and the building may be so formed, and the materials so disposed, as to give a picturesque and decorated effect, without the use of any expensive ornaments. The desired effect will be given, by the tall chimneys by the high pointed gables, with, perhaps, small pinnacles at the angles; by the mullioned windows and the labels over them; by a projecting porch of one or two stories; and by the stringcourses round the building. In this style much of the ornamental work might be of wood. For instance, the whole of the upper story might be formed of a wooden framework, filled in with brick or plaster. This wooden framework would project beyond the wall which supported it, and produce a pleasing effect of light and shade, and a variety of ornament might be given by the form of the frame work, which shows on the outside, and by the arrangement of the bricks, or by the patterns impressed upon the plaster, with which the interstices of the frame are filled up. In these half timber houses might be introduced a kind of wooden oriel window which is one of the most striking ornaments in many old cottages. The gables over such a building might be handsome half boards with carved pinnacles at the points. These pinnacles, if small and in good proportion, would be in keeping with a mode of building which admits of a great variety of embellishment and is well suited to a district where stone and other substantial materials are scarce and expensive. As it possesses these recommendations, we will adopt the old English style for our present purpose, and suppose the cottage erected on a dry, airy site, well protected from the prevailing winds and surrounded by its garden, orchard, and out-buildings. It would of course present one regular front. This we will suppose divided into two equal parts, each with a porch of two stories in the centre: in the ground story of the porch might be an arched entrance; in that above, a neat mullioned window of two lights, with its proper label; and over this a low gable terminating in a simple ornament. On each side of the porch might be a mullioned window of three lights, placed immediately under the stringcourse, which divides the house into two stories: the low wall above these windows would be plain, as the windows of the rooms in the chamber floor would be most conveniently placed in the gables at the ends of the house. In the centre of the roof, behind the porch, would be the stack of chimneys, which should be tall and rather the handsomest member of the building. It is the most conspicuous part of it, and the general effect of the whole would depend materially upon the form of the stack of chimneys. This front would afford an example of what I understand by picturesque simplicity. There would be a certain symmetry and unity about it. It would present no superfluous ornaments, nor any unbecoming irregularity. But still it might be made a highly ornamental cottage, and might contain many internal conveniences which are not always found in buildings of more pretension, and it would possess enough of the picturesque character to make it harmonise with the surrounding scenery.

**§222. Exterior accommodation.** Such, then, would be the exterior of the cottage: what are the accommodations it should contain within? A comfortable labourer's dwelling should in my opinion consist of an entrance porch, kitchen, washhouse, entry and small cellar, a parlour or spare sitting-room and at least three bedchambers. These apartments are all necessary for the comfortable accommodation of a family even in humble life; and, as we are attempting to describe the *best ideal* of a cottage, we must suppose it to contain all these conveniences which we proceed to describe in their order. A porch, besides being an important ornamental appendage to a cottage, is necessary for the comfort of the inhabitants to which it contributes by sheltering the entrance from wind and rain, and thus assisting to warm the interior. A cottage porch should be of small dimensions, the floor on a level with the rooms within, and raised a step or two above the surrounding surface. It should be paved and celled, and if it had a seat on each side, it would form a kind of summer-house, where the females would often sit at work in fine weather. Over the seats might be shelves, on which small tools might be put away and seats, ovens &c placed to dry. There should, of course, be a scupper at the steps, and a mat within the entrance.

**§223. Kitchens.** From the porch you should pass through a small lobby to the kitchen, or common sitting-room of the family which should be a sufficiently spacious, light and airy apartment. The object of the lobby is that there may be two doors between the living room and the outer air which will assist in keeping the room warm with a less expense of fuel. There are some defects usually found in the interior of old cottages, which ought to be avoided when new ones are erected. I allude to the lowness of the rooms and doorways damp floors and smoky chimneys. If we were to judge of the people by the houses they inhabited, we might suppose the former generations of our bold peasantry their country's pride, to have been absolutely a race of dwarfs. For if you would avoid a broken head you must actually creep through the doorways of ordinary cottages and after escaping the perils of the doorway a man of good stature can seldom stand upright in the house without being in danger of knocking his head against the bare rafters of the floor above, or against the bacon-rack, the scythe-blade, the rearing-hooks, and twenty other things commonly suspended from the ceiling. Now these low rooms and doorways must be a continual source of annoyance to the inhabitants; and therefore, I would lay it down as a general rule that no cottage kitchen should be lower than eight feet, and every cottage doorway above six feet. Another common defect in cottages, is the dampness of the ground floor. In the case of old cottages, the ground floor is usually much below the level of the surrounding surface and you generally descend into the house; and, even in modern cottages the floors of the lower apartments are seldom sufficiently elevated. The consequence is, that, in many situations, the cottages are damp and uncomfortable for five or six months in the year; indeed, I know several cottages in which springs of water regularly break through the kitchen floor during the winter season. To avoid this inconvenience, I would propose, as another general rule, that the ground-floor of every dwelling of the description should be at least six inches or more above the surface, and that the earth on the outside should be the same distance below the level of the floor. Under every brick or stone floor there should be a substratum of broken stone or flints, varying in thickness according to the nature of the soil and situation. On a damp site it may be necessary to have this substratum two or three feet deep, with drains and air passages through it; and the earth should have a good slope from the walls on every side so that the water from the roof may escape rapidly and not sink into the foundation. Another prevailing misery in cottages is, a smoky chimney. This is a proverbial nuisance to every one; but it is especially so to a cottager because, ever and above the dirt and discomfort occasioned by the smoke, half the fuel is wasted in a fireplace which has not a proper draught. This nuisance in cottages generally arises from the large size and straightness of the flue, and from the lowness of the chimney on the outside, or from the currents of air occasioned by the bad positions of the doors and windows which seldom fit close. From whatever cause it arises, a smoky chimney is a prevailing misery in labourers dwellings which a judicious builder may generally contrive to avoid; and I refer the reader to some sensible observations upon this subject in the *Elements of Cottage, Farm, and Villa Architecture*. After this digression, let us return to the cottage kitchen. As this is the common sitting-room of the family in which most of the household operations are to be performed, it should be a light warm apartment of a good size. We will suppose it sixteen or seventeen feet square and eight feet high, having a window in the east and one in the west side. It would

must have the benefit of the morning and evening sun; an important advantage to a cottage, in whose domestic arrangements cleanliness and order are considerable articles. Stone is I believe, the best material for the floor, as being most durable and easily kept clean and in these respects greatly to be preferred to brick. Boards, however, that they are liable to constant accidents by fire, could scarcely be kept clean in a cottage living-room, and would soon be worn out by the foot-boards of the inhabitants. Of course the walls and ceiling should be nicely plastered and whitewashed, and there should be a proper skirting-board round the room, and attached inside shutters to the windows. The fireplace should be so situated as to be well lighted by one of the windows; and it might be a close or open fireplace according as wood or coal happened to be the common fuel of the district. I observe that the old-fashioned open fireplaces are generally preferred by cottagers, on account of the snug warm seats they afford in the chimney corner, as it is called, and which is too often the only warm place in the house. I am aware that these fireplaces do not economize fuel, or afford the best means of warming the room; but they present some advantages to the cottager; that is, they are capital places for drying bacon and wet clothing. Either wood may be burnt in them on the hearth, or coal in a movable grate; and, as the fire is on or near the ground, it certainly diffuses a considerable heat around it. The mouth of the brick oven also generally opens in the back, or side of the chimney so that all the ashes and litter together with the heat produced, are confined to one place; and, should this place be near the centre of the building the mass of warm incense must have the effect of raising the general temperature of all the apartments. In the coal countries these open fire-places are not usually met with; but, where wood is the principal fuel of the peasantry (as it is in the district from which I write) I would indulge their prejudices in favour of an open chimney and will suppose one in the cottage kitchen, with the mouth of the oven on one side of the back, and on the other a small copper set in such having a flue through the arch by which the steam might escape up the chimney. It would be tedious to describe minutely the various articles of useful and ornamental furniture found in the kitchen of a thriving cottager. Indeed, to those unacquainted with rural life it would be difficult to convey an idea of the miscellaneous collection often displayed in a room of this kind. A tidy labourer's wife is sometimes as fond of knick knacks and as proud of displaying her various stores, as the richest lady in the land. The peasantry have, in fact, many of the prevailing tastes of their superiors in wealth and refinement, and love to ornament their houses with plants and flowers, prints, and plaster casts and ornamental china. The kitchen is frequently as much crowded with useful and ornamental furniture as a modern drawing-room. The mantel-shelf displays a range of flower-vases, images, and painted busts of the favourite heroes of past and present times, mixed with some of the bright cooking utensils. The walls are sometimes thickly hung with coarse engravings, ballads, and printed papers, moral, religious, and political, and with various other things, among which are conspicuous the labourer's club rules and his staff, or some peculiar implement denoting his occupation, such as the polished head of the shepherd's crook, the marked day carrier's whip, or the spare tail of the thrasher. The window is seldom without its collection of crochets, carving-surprisingly some of them in spoutless teapots and other discarded vessels and on the window seat, or on a shelf near a pile of books; the table, in a neat cover reverently placed apart from the rest. Even the ceiling is usually furnished with that desirable ornament, a well-stored basket-rack, where tools, bags of seeds, and a host of other things. But the pride of the cottage housewife is her dresser and shelves. Here she displays her little store of glass and earthenware of the better kinds with her best plated spoons, her bright pewter plates, and clean wood trenchers, frequently arranged with considerable taste and effect. Some of the conspicuous articles will not perhaps bear a close examination and are, in fact, only kept for show; but she contrives to hide defects, and the shelves often exhibit specimens of old glass and china, which a collector of such rarities might covet. There are, indeed, few more picturesque interiors than that of the well kept kitchen of a thriving labourer who happens to have a tidy wife and I have often been much pleased at the air of decent comfort, and at the decorated effect produced by the miscellaneous collection seen in a room of this description.

**824. Furniture of the kitchen.** Among the more prominent articles of furniture in a thriving labourer's kitchen, the clock, I think, takes precedence of the rest in the owner's estimation and its well-polished case is generally a conspicuous object. Next to this we may rank the best dining-table, often one of those interesting old oak tables with rounded leaves, and as many curiously-turned legs as a spider. The best tea-table turned up, with its pillar and claw in a corner, and the dough trough with its clean white cover, would next attract attention. To these we may add the great straw-chair with a patchwork cushion in the bottom, for the even, as he is emphatically called here in which he sits in the evening in a sort of rustic dignity, surrounded by his wife and children, forming in many cases, a happy interesting group. The wife and eldest girls at work perhaps while one of the boys is standing by the fire reading, or repeating what he has learnt at school during the day. I hope there are many such evening groups still to be found in our cottages, in spots of politics and the beer shops. This reminds me of another piece of furniture which I should wish to see in every cottage. I mean a shelf of useful and instructive books. You seldom enter a cottage without finding some books; indeed, as far as my observation extends, I should say that a taste for reading is becoming more general among the labouring classes and it ought to be encouraged, as a source of instruction and enjoyment, which has a tendency to improve the morals and better the condition of the peasantry. What a wide field of knowledge and enjoyment is cut off from the labourer who is unable to read, or who has no taste for reading! Half the leisure time of such a person must be spent in drowsy indolence, or in the debasing scenes of the ale-house to which he is almost driven in self-defence to relieve the tedium of idleness and the oppressive vacancy of his mind. The want of this resource and comfort is severely felt by the uneducated labourer in times of sickness and old age, when a long active life is necessarily exchanged for a state of total inactivity. There are few of the rising generation entirely without education. The stores of knowledge will therefore soon be opened to all the labouring classes, and they should be encouraged to use them to their own advantage, by having their attention directed to useful and improving books. A little learning is not properly directed, it is a dangerous thing.

**825. Back-stairs and washhouse.** Besides the kitchen, or common living room of the family every complete cottage should have a small washhouse in which the brewing and washing, the dirty and all work of the family may be done. Here I would have shelves for the spongers and other unsightly articles, used in cooking; also a small copper, and a proper sink, communicating by a drain with the dung pit or a cess-pool. Most cottages are without a washhouse; but a small place in this sort is absolutely necessary to every dwelling; and, without it, the living-room can never be tidy or comfortable and, I may add, wholesome. For want of a washhouse, the cottager is compelled to hang up his dead pig, and even to salt it, in the living-room; and as there is no other place in which to do the dirty work and put away the dirty things which must be used in every family, the room is generally in a litter and has an unwholesome, disagreeable smell, which must be prejudicial to the health of the inhabitants. But what I would chiefly insist upon in the washhouse is a proper sink to receive the slops and dirty water. Very few cottages have any convenience of this kind; and consequently all the slops are thrown out at the door; and you can scarcely approach a cottage, in many cases, for the abominations that surround it. Besides this, the entrance is constantly surrounded by a sort of impure air which is extremely offensive, and must be injurious to the inmates. No cottage, therefore, should be without a sink, communicating with a drain, which may carry the dirty water to a sufficient distance from the house. Even a poverty cottage will have a small tolerable convenience, when the door is surrounded by dirt; and I have seen villages, with the houses built on each side of a narrow road, which were distinctly disgusting in consequence of the nuisance referred to.

8228. *A small larder or pantry, having a window in the outer wall, should communicate with the kitchen or wash-house.* This is a necessary convenience not often found in labourers' dwellings, in which the provisions are generally kept in nasty close cupboards, or on shelves in the living-room, where they are liable to get spoilt, and are exposed to dust, smoke, and all sorts of impurities. For want of a better place, even the beer or older barrel is kept in the warm kitchen, and in such a situation the liquor of course soon becomes sour and unfit to drink. A larder, therefore, should be without a good airy larder and a small place of this kind might be easily contrived in every dwelling, with little or no addition to the cost of building. As I am describing the *base ideal* of a cottage, the owner of which might keep a cow I will, in the present case, suppose the larder of a sufficient size to contain both the milk and provisions. We can scarcely expect a distinct place for each in a labourer's cottage, and it would be unnecessary. There might be separate shelves for the milk and provisions, and hanging shelves for the small cheeses, which a managing woman would of course make during the summer season, even from her single cow.

8227. *Cellar.* If the floor of the larder were sunk the depth of a yard below the surface the beer might also be kept in it. But a cottage would not be quite complete without a small cellar to contain the beer and the potatoes and other roots. A cottager with land would grow a large supply of potatoes and other roots, for his cow and pigs, and it would save a great deal of time, and prevent waste, to have the roots always at hand in the cellar instead of burying them out of doors in pits, which when once opened, are not secure against frost and wet. I would also recommend a cellar in every new cottage, because I look forward to the time when every labouring man will be able to brew his beer at home. A hard-working labourer requires a certain quantity of wholesome beer, and if he has not this at home, he is sure to go to the alehouse, where he gets into the worst company, spends in intemperance what is required for the maintenance of his family, and in many cases becomes a confirmed drunkard. It would be a work of charity therefore to encourage brewing among the labourers, and, as a means of promoting it in country villages, I would suggest a plan of having a small set of brewing utensils for the use of the cottagers, in the care of a fit person, who would lend them, in the parish under proper regulations. The cost of the tubs &c. would be inconsiderable, and might be easily raised by subscription among the wealthy inhabitants, or even among the cottagers themselves. A penny or two paid for the use of the tub would be sufficient to keep them in repair. The want of tubs is one of the chief obstacles in the way of cottagers brewing, which this plan would remove. And I am persuaded it would succeed, as I find that even a whitewashing brush, kept to hand out, has been a great promoter of cleanliness.

8228. *The parlour.* Should this paper ever fall into the hands of a labouring man, he would probably smile when he came to this part of it, in which I am to speak of the parlour. Many persons will consider a parlour an unnecessary luxury in a labourer's dwelling. It would be seldom used perhaps as a sitting room, but as a spare room it would be a great convenience in the case of a large family, and should not be omitted in an attempt to describe a complete cottage. Most thriving labourers are in the habit of receiving their distant friends and relations, at certain seasons, such as the village fair, at the times at Christmas &c. The parlour would be useful on such occasions, both as a sitting-room and additional bedroom, as it would be also in case of sickness or death. If for no other reason I should be an advocate for a spare room of this kind in every cottage, as a receptacle for the dead. As cottages are at present, there is seldom any possibility of separating the dead from the living, when one of the inmates dies, when such a calamity occurs, the corpse must be placed either in the sitting room or bedroom, and I have known instances of a large family sleeping for several nights together in the same room with a corpse, even when death has been occasioned by an infectious fever. To my feelings there is something unspeakably terrible in this dreadful mixture of the living with the dead, and if the idea be so appalling, what must the reality be to those who suffer it! A small parlour, therefore, containing an occasional bed, would prevent the necessity for this most disgusting consequence of death in a labourer's family, as with the possibility of making up an extra bed for some of the inmates one of the bedrooms might generally be appropriated for the reception of the body between the death and the funeral. I would have the parlour a plain comfortable room, ceiled and plastered, with a pane or boarded floor. It should of course, have a small fireplace and attached inside window shutters. Besides the chairs and table, the furniture should comprise a closet bed complete, as the room would probably be more used as a bedroom than as a sitting room. A corner cupboard to receive the best china and glass, a few groceries, &c. would also be useful, and a chest of drawers for the linen of the family would not be out of place. I should whitewash the walls, because it could be done by the cottagers themselves when requisite, and colour washing is, of all things in this way, the most difficult to do well to the uninstructed. The cottager's wife would decorate the walls and the room generally with some of her best knock-knacks, books, flowers, &c.

8229. *Staircase.* As we proceed to the upper story we must say something of the staircase. This, in old cottages, is generally the most awkward thing possible, and placed in the most awkward situation, a narrow twisting dark, and to a stranger a dangerous ascent compared with which a common ladder would be luxurious, and usually leading into a bedroom which is a passage room to another, when there happens to be two. Our cottage must have a proper light staircase, ending above in a small landing, to which all the bedroom doors should open.

8230. *Bedrooms.* Every cottage for a family should have at least three bedrooms, so that the parents, and the children of each sex, might sleep in separate apartments. The rooms need not be large, but they should be light, airy comfortable, each having a window that will open. They ought to be ceiled, plastered, and whitewashed with boarded or plaster floors, and, if possible a fireplace in each, in case of sickness or merely for ventilation. I am rather an advocate for the plaster floor used in the north of England for cottage bedrooms, as they are a security against accidents by fire, and when properly made, are more comfortable and have a more cleanly appearance, than the rough ill-jointed boards commonly found in cottage chambers. I have seen these floors nearly as hard as stone, and when washed over with slipcase they have a very neat effect. It is unnecessary to describe the furniture, which of course, should comprise the requisites for comfortable repose and cleanliness in a humble way. You seldom find bed-curtains in a cottager's chambers; I have heard them express a dislike to bed-furniture and, in a tolerably warm room it is, I think, a luxury we might all dispense with, as being rather prejudicial to health than otherwise. Cottagers generally use stumpy beds, with head-boards, and I have observed in cottages ancient specimens of oak bedsteads, with curiously carved head-boards and legs. Old carved oak clothes-chests are also frequently met with, which would be valued by the antiquary. There are few things connected with labourers' dwellings, which so much need reform as the bedrooms. In this neighbourhood half the cottages have only one chamber and this sometimes a low miserable apartment in the roof, open to the thatch, with the walls unplastered, and without a window that will open. In fact, a place little better than a hay loft. And here the whole family sleep, old and young married and single, without even a curtain to separate the sexes. Can we wonder at the gross immorality which is so lamentably common among the young peasantry when the sense of decency is destroyed even from infancy? I would therefore press this subject on the attention of all benevolent owners of cottages, and especially on our great landed proprietors, who are generally well disposed to contribute to the improvement of the peasantry. The first step towards the improvement of their tenants must be to increase the number of bedrooms in cottages. Let me, then, urge this upon those whom it concerns, in the words of a *Wesley's* sternest preacher yet the best, the poet Crabbe:—

These thoughtless people part,  
Nor let the ear be first to take the heart."

832L. *General remarks on the interior.* Having described the interior of the cottage, let me pause and enquire, whether there is any thing in the description which can be justly considered superfluous, and not absolutely necessary for the comfortable accommodation of a labourer with a large family. I am not aware of any thing to which a reasonable objection can be offered unless it be the parlour. The idea of a separate parlour may lead some to exclaim, "The man must be a fool! Who is to do the work? If labourers are to be sent there, and sit in parlours?" My friend, are you not offended at a man? Let us change the high-sounding title of this room of all works, and perhaps you will not object to it. Call it the spare room, for instance; a place to be used for all sorts of purposes for such it would be, in fact. Unless when the wife was confined, or any of the family happened to be recovering from illness, I will answer that it would not be used as a parlour above six times in the year. It would frequently be let as a lodging to an occasional labourer in the parish. In rainy weather it would be degraded into a drying-room and be filled with wet straw; and the floor would often be found half-covered with onions and *scall* laid there to dry. Do not the various uses to which such a room may be applied make it a desirable addition to a cottage, even though it may be called a parlour? If such an apartment would have a tendency to give the peasantry fine notions, I should be the last to recommend it. For I hate fine people of all sorts, and the poor people above all others, because they have not even an excuse for being. But though I would not give them notions unsuited to their station, I should be glad to see their habits improved, and I know, from painful observation that our cottages stand in need of improvement. They are in fact, behind the times, and while the houses of every other class of society have been gradually increasing in comfort and convenience, the dwellings of the labourers are little better than they were a hundred years ago. Many improvements and conveniences in cottages have been suggested by others which I forbear to notice. For this reason, that while such conveniences are attainable by persons of small means and property it is in vain to expect that they will be provided for cottagers. My object has, therefore, been to describe the accommodation required in what would be called a comfortable labourer's dwelling, and to suggest practicable improvements which are likely to be effected; and I hope that there is nothing in the foregoing description which can be considered impracticable.

833. *External appendage to a labourer's cottage.* I am now to speak of the external appendages to a complete labourer's dwelling including the yard and out-buildings, the garden, orchard, and allotment of land. To account for some of the out-buildings which will be mentioned in the following description I must remind the reader that, as I am speaking of a cottage of the first class I must, of course, suppose the cottage to keep a cow; and that, besides a quarter or half an acre of land, for spade husbandry (the quantity should be proportioned to the spare time of the labourer and the quantity of manure he can collect,) he would also be the possessor of about three acres of pasture. I am of opinion that it would have a beneficial effect upon the general conduct of the agricultural labourers, if there were a certain number of cottages, with land attached to them, in every parish to act as a sort of stimulus to industry and frugality. Formerly the small farms presented this stimulus. The industrious sowing cottager had then a chance of rising a step above his original station in society; and a natural desire to improve his condition would act as a constant inducement to carefulness and activity. But now he has no such inducement. In most parts of England, parishes which were once divided into ten or twelve farms of various extent, are now thrown into two or three large ones; the waste lands are enclosed or appropriated, and even the bare-worn commons is in many cases devoted to the hard working frugal labourer, who happens to have saved enough money to set up a cow. How can we wonder then at the careless imprudent habits of the peasantry when they have scarcely an inducement to be otherwise? But, under all their disadvantages, there are many who are worthy, and it is not rather hard that they should be deprived of the opportunity of employing it profitably in the out-buildings with which they are acquainted, that is, agriculture? Let us suppose a working man to be possessed of £1. Almost the only way in which he could invest it safely would be in a savings bank where it would produce him an interest of about 3s. a year. Now this is all very well; the principal sum is secure, and a certain 3s. a year is a desirable addition to a labourer's income. But it would take nearly his whole life to save up £1; and half that sum would produce a much greater income, and much improve his condition, if employed in some sort of business. In short though the savings banks have been a great benefit to the working classes, the small income produced by a sum of money placed there does not afford a sufficient stimulus to frugality. The interest upon their savings can add little to the comforts of the depositors; and, as to having a sum of money against the time of sickness or misfortune, they know that the parish must then support them; and though they might be induced to save, if by saving, they could materially improve their condition, we must not expect them to save for the relief of the parish. Let us suppose a man to have saved only 25s., and to have an opportunity of taking a cottage, with land enough attached to it to support a cow. He would probably invest his little capital in a cow, a couple of pigs, some poultry perhaps, and a hive or two of bees; and, if he had tolerably good luck, and were a good manager, he would soon be placed in circumstances of comparative affluence, and would be infinitely better off with his 25s. than formerly, than the other would be with his £1. In the savings bank. The great improvement in his condition would also be apparent to all around him and would act as a powerful spur upon the carefulness and industry of his neighbours. Money in the savings bank would not produce this consequence, because its effects are less apparent; in short, its effects are unimportant when compared with the comforts derived to a labourer's family from keeping a cow. But, besides being prius to excite the diligence and reward the good conduct of the labourers a few cottages, with land attached, would be a general convenience to the villagers as a means of supplying them with milk; a luxury which, in my neighbourhood, is seldom tasted by the poor. Though living in the country they are worse off than townpeople in this respect, as they cannot get it for money unless on some particular occasions. The cause of this inconvenience is the large farms and the want of cottages a cows. A rich farmer is, of course, above selling milk, and there is no one else to sell it, unless there happens to be a small farmer in the parish or the rich farmer lets his cows to the farmer or dairyman. It would not answer to sell milk in small quantities; and, as we have no cottage centrepiece, the peasantry are deprived of a nutritious article of food which it is almost impossible to do without. Whenever there are no cottages a cows, the peasantry in general must be ill supplied with that important necessary milk. I offer these reasons for the opinion I have ventured to advance that in every village a few cottages with land to keep cows would be desirable on many accounts. I do not say that every cottager should have a cow. Perhaps it would be better if all had them who can manage them; manage they would be found, upon trial, that the number of these would not be large. A cow would be thrown away upon dirty indolent cottagers, and there are many respectable ones so situated that it would be more an inconvenience than an advantage to them to keep a cow. But I think there should be a few cottages with land in every parish that the steady and industrious, and those who have an opportunity may at least have a chance of improving their condition.

833L. *The garden.* After this long digression, let us proceed to speak of the yard, a very necessary convenience to a labourer who keeps a cow. The washhouse should have a door opening into the yard, which ought to contain the pump, dung-pit, and all the out-buildings. The pump I would place as near the washhouse door as convenient; the dung-pit in the corner of the yard farthest from the house; and to this pit the surface of the yard should have a gentle fall. It should, of course, be properly drained.

834. *The fuel-house.* The first out-office to be mentioned is the fuel-house, a place in which the coal and dry wood may be kept, if necessary under lock. The tools and haywain bits, and many other things may also be placed in this building, which is a necessary appendage to every cottage. It would be most conveniently placed joining the back part of the house, so that it might be approached without cover from the washhouse door.

6228. The cow-house and pigsty should be near the dung-pit, that the drains from both may be led into it at little expense, and to save the cottager's time in cleaning out the cow-stall, &c. The cowhouse need only contain one rosey stall and a calf-pen, with a small lot over both for the hay brought in by the waggon. The pigsty to a cottage where a cow is kept should be divided into two, that the stove-pig, which a good manager would never be without, might be separated from the fattening pig.

6229. If a poultry-house should be required, I would place it either over or adjoining to the cowhouse, for the sake of warmth. But I am not sure that it would answer to a cottager to keep much poultry unless in situations where there is a ready sale for eggs and chickens, and where poultry can be kept without being a nuisance to the owner and his neighbours. In a widely scattered village this may some times be the case, but where the houses are near together the cottager's fowls are a continual source of dispute and annoyance. They are ill-fed at home and cannot stray any where in search of food without trespassing upon a neighbour's ground, where, in the absence of the family at work, they may devour or destroy half the produce of the garden. Where the houses are scattered, and a cottager has land of his own or is near a common, on which they could have a run without trespassing upon others, perhaps it would answer his purpose to keep a few fowls; that is, if he can keep them out of his garden but not otherwise. If water is near ducks would be most profitable to a labourer and more easily managed than hens.

6230. Piggery. I do not recollect any other out-building actually necessary for the cottager's convenience, unless it be the privy which might be either in the yard or in the garden and if desired, I see no objection to one in each place. But it is useless to talk of a separate convenience of this kind for males and females, till every labourer's dwelling has one. I believe that nearly half our cottages are without any place of the kind; at least it is so in my neighbourhood. For instance, out of sixteen dwellings near me, six only have the convenience alluded to, and three of the six conveniences have been erected within these two years. The want of such places must be a terrible nuisance to the cottagers, and I particularly recommend the subject to the attention of cottage owners.

6231. General observations on enclosures. As the fence of the yard and the outbuildings would add something to the cost of the cottage I choose here to meet objections that I suppose and recommend only the least expensive out-buildings, such as the cottagers, with trifling assistance, would very frequently erect themselves. The cowhouse would be the chief expense, and that would be little better than a common shed, walled up with any thing on three sides and open to the south. But I would have a strong fence and gate to the yard to be fastened well at night, that all the stock may be secure, as it would probably cost the owner at least a day's work when his cow or pig happened to get astray. I do not mention any place for pigeons in the yard, because a cottager could not keep them without constantly trespassing on his neighbours. There is an increasing prejudice against pigeons which are certainly very troublesome to the farmer at certain times in the year. Doves are now much less frequently seen in farmyards than they were formerly at least in the corn growing districts, and if the farmers can no longer keep pigeons, of course the labourers must not. Where the cottage stands near a common or among open green lanes, it would answer the cottager's purpose to breed a few geese which are a profitable kind of stock, because, after a certain age they almost take care of themselves. They would require to be secured at night; and, if the cottager keeps geese, he must add a house for them to his out-buildings in the yard.

6232. The garden, if well managed, is commonly the most striking feature about a labourer's dwelling, and there are many reasons why it should adorn the house. In the present case we will suppose the cottage to be surrounded on two sides by the garden, and I would approach the front of the house through a narrow part of the garden which divides the house from the road, and the part of it I would devote chiefly to flowers and shrubs. I would train some ornamental climbing plants against the walls of the house and a vine or pear tree if there were proper situations for them where the fruit would ripen, and be out of the reach of the children. I observe, however, that, excepting vines, fruit trees seldom thrive much against the walls of cottages. There are few labourers who know any thing of the art of pruning and being improperly pruned, the trees bear little, and seem not worth the time and trouble they require. However, do remarkably well against the cottage walls in this neighbourhood and bear profusely in many situations, apparently with very little care or pruning. I am not qualified to lay down rules for the management of a cottager's garden but I would venture to suggest that it should not be too large. A small garden, well cultivated, being more profitable than a large one half cultivated. In fact if he have an allotment of potato ground elsewhere the cottager has no use for a large garden, as he grows and uses none but the commonest vegetables, which take up little room. He does not ever cultivate much small fruit. Strawberries and raspberries are very seldom seen in a cottage garden, and currants and gooseberries are not often abundant; so that a large garden is not requisite. I used to wonder formerly why the cottagers did not cultivate the small fruits in greater abundance, as they require so little trouble and are so extremely useful. The reason for this neglect, given me by several labourers, is, that the children devour the fruit before it comes to perfection. In fact, they begin upon it as soon as it is formed, and very little is left to ripen. As cottage children are, of course, left a great deal to themselves, I believe it would be useless to attempt growing fruit where there is a large family, or in a closely built village. Where a cottager therefore, cannot grow fruit, he ought, I think, to keep bees as a substitute for the profit of fruit. Indeed no cottage garden should be without bees, placed in some warm retired corner at a short distance from the house, for they are not agreeable neighbours. Bees are, I believe, the most profitable of all stock for a cottager as the whole of their produce is valuable and, except at swarming times, they are no trouble.

6240. Orchard. Besides the garden, it is desirable that every cottage with land should have a small orchard attached to it, especially in the silder countries and in extensive allotments of land, there are generally rough plains, which being of little value for any other purpose, might be converted into small orchards. Where there is no waste place of this description I would plant the orchard immediately behind the garden and contiguous to the house, that it may be easily overlooked by the owner. I would also rear a good hedge round it to keep out intruders, for young cottagers are so fond of sour apples as they are of sour gooseberries and though they can scarcely clear an orchard of apples as they would a garden of small fruit, they will do a great deal of mischief if not guarded against. As it is scarcely possible to have too much fruit, and a peasant's orchard is not likely to be large, I would plant some fruit trees in the hedges of the garden and fields. Damsons and elder apples, and other common fruit trees, would do very well in the hedges, and would be very ornamental. I think a cottage orchard should produce apples, pears, and plums of various kinds, but chiefly apples. Fruit will sell every where; and it is desirable that a cottager should have as many ways as possible of making a little money. The landlord ought to furnish the cottage grounds with fruit trees and a gentleman of landed property would do this at a very trifling expense, by having a small cottage nursery in which his gardener might graft and rear fruit trees of good kinds to be transplanted, when fit, into the cottagers' gardens and orchards. Many labourers are fond of grafting, and, if the ground were planted with fruit trees at first by the landlord, the tenants would generally keep it stocked. I wonder our landlords do not see the advantage of placing their cottage grounds with fruit trees by which they would increase the value of them, and place in the hands of the tenant the means of paying the rent. They would also give their cottagers an additional comfort, and greatly increase the beauty of our villages, by surrounding the houses with fruit trees which are the most interesting of all trees. What can be more beautiful than a handsome apple tree which are the most interesting of all trees. What can be more beautiful than a handsome apple tree covered with ripe blossoms in the spring or loaded with golden fruit in autumn? It is picturesque even in winter when its rugged mossy stem and irregular branches are exposed to view. Indeed, a village with many small orchards about it is generally a pretty village.

**8361. Potato-ground.** The next thing to be spoken of is the allotment for potatoes, &c., without which no cottage could, in these days, be thought complete. But, of course, this allotment would be much smaller in the case of a cottager keeping a few pigs in that of a labourer with only a garden to attend to. The cottager would have many little odd jobs to do connected with his cow and land, which would leave him but leisure enough to cultivate an extensive potato-ground besides his garden. Nothing pays a labourer so well as working for a master; consequently a garden cannot answer to a cottager if he is obliged to lose time, as they express it, in order to cultivate it. A cottager's ground for potatoes, &c., should therefore be smaller than that of another labourer, because the man will not have much leisure, and the wife will have less, as she will have the produce of the cow to manage, in addition to the ordinary cares of the family. But if the cottager have not constant employment with a master, the case would be altered and he would require as large an allotment as other labourers. He would probably cultivate his ground on a different plan from that followed by ordinary cottagers. He would not have space for a plot of corn, and it would answer his purpose better to grow cabbages, Swedish turnips, man-gold warran, or something that would be useful for the cow, on that part of his ground not occupied by the potato crop. Indeed, a man who has a cow and pigs should consider their wants in his gardening almost as much as does those of his family, and his pigs should nearly live on vegetables during the summer.

**8362. Grass land.** We conclude with a few observations upon the grass land which the cottager is to occupy for the use of his cow. This should be about three acres, divided into two enclosures. I believe three acres of fair grass land are generally considered the quantity required in summer and winter a cow; but, if a less quantity would be sufficient, of course the cottager would not desire more, as it would cause an unnecessary addition to his rent. He had better have rather too much land than too little, as the profit of a cow depends in a great measure on its being well fed. He would probably sow his fields for hay alternately as he would not be able to mow very freely. He must, however, mow a portion of his grass land every year or it would go back. And, if he were a good manager, he would be able to do this; for it is surprising what a heap of compost a managing person will collect who keeps a cow, and two or three pigs, and gathers every thing that can be converted into manure from the garden, the yard, the drains, and the roads about the premises. If he had not too large a potato-ground, a cottager situated as I have described, would not be a good manager if he could not contrive to dress over an acre of his grass with compost every year, and this would be sufficient to keep it in heart if it were mowed every alternate year. There is one thing connected with allotments of land to labourers, which I would press on the attention of cottage owners, that whatever land is let to a labourer should be adjacent to his house. It should be remembered that the cottager's land is to be cultivated during the leisure time he has after having done an honest day's work for his master. His land, therefore, should be near his abode, that he may make use of all his time, half of which would be wasted in walking backwards and forwards if his land happened to be at a distance. If, also, his land were at home, he would spend many a half hour speding thistles, or spreading dung in the field, or doing many little odd jobs which would be left undone if the land were some way off. Moreover, it works a man too hard to have to walk a quarter of a mile or more, to his extra labour after, perhaps, walking a much greater distance from the place where he works for a master. He would do half as much more work, and do it with more pleasure to himself, if he could do it at home, where he could immediately retire into the house when he felt fatigued. In short, if a cottager is to do any good with land, it should be within an easy distance of his home. Imagine the extra labour occasioned to the cottager when he has to wheel out the manure, and bring home the produce of his land, distant, perhaps, a quarter of a mile from his house. Where the cottage belongs wholly to one proprietor who is the principal landowner in the parish it may generally be contrived that the allotment of land may adjoin the cottage, or be at least a convenient distance from it. A cottager can generally afford to pay as good a rent for land as an ordinary farmer; and, if he can afford to pay for it, he may reasonably expect to have it conveniently situated.

**8363. General observations.** I believe I have noticed most of the conveniences, internal and external, which in these times would be thought requisite to form a complete labourer's cottage. I am aware that the description given goes very far beyond the ordinary run of cottages, as they are at present. My aim has been to make it so, but I hope I have suggested nothing but what is absolutely necessary for the decent comfort of a family. My aim has also been to speak of practical improvements; and to show how the domestic accommodations of the peasantry may be increased at a moderate expense. There are many desirable improvements and luxuries suggested by writers on cottage architecture, which I have forbore to mention, for this reason, because costly improvements are not likely to be applied to cottages; and it is needless to recommend luxuries for labourers' dwellings, which are not found in the houses of wealthy farmers and tradesmen, and even in those of the smaller gentry. Our peasantry however have no desire or taste for luxurious habitations. They wish for comfortable cottages that is, dry, warm, and, above all, sufficiently roomy dwellings in which their families may be conveniently accommodated, without violating the common decencies of life. If they had houses of this description, they would have every reason to be satisfied and would be so without unnecessary luxuries. And I hope the time is fast advancing when the improvement which has taken place in the habitations of all classes above them will be extended to labourers' cottages.

**8364.—8365. Asphelt** as the upper layer of the floors of cottages effectually prevents the rising of damp; as it also does when introduced in a thin layer in a wall, a little above the surface. (*G. M.* 1846 p. 564.) It has as we have already mentioned (**8316**) been found to form excellent barn floors.

**8365. Design for a three-plough farmery** by Mr. Mackenzie of Perth. Fig. 1171 is a ground plan, *Fig. 1172*, an isometrical view and *Fig. 1173*, a vertical profile. This three plough farmery is understood to be built upon level ground; with the straw yard cut out hollow in the centre of a basin figure, that being the best form for retaining the moisture among the manure. In fixing the position of the different ranges of the buildings, the highest are put down to front the north and east, as best suited the purposes to which those parts of the farmery are to be applied, and at the same time adding to the comfort of the cattle in the sheds and straw yards, by sheltering them in the directions which are generally the coldest.

**8366. The byre** (*c, d*), which are low buildings on the west and the pleugas (*e*) which are on the south, do not shade the straw-yard and cattle-sheds but admit the rays of the sun to all parts of them. The farm-house is supposed to be situated on the south west of the farmery with the kitchen court adjacent to the cow byre calf yard, &c.; thus keeping the offices which are managed by the house servants in one division, and those under the management of the farm servants in the other division of the establishment.

**8367. The threshing machinery** (*f*), being placed in a corner of the square, discharges the threshed corn into the clean corn-room (*m*) in the direction of the granary, which occupies the upper story of that side of the square; and the straw is thrown from it into the straw house which is in the direction of the straw-chamber, over the feeding-byre, stables, &c., on the other side of the square. The clean corn-room thus communicates with the granary which extends from this point over the cart-shed. In this way the clean corn-room and granary occupy a side of the square apart from the offices allotted for the cattle, and the other apartments connected with them; and, as the corn-room can be locked up the present operation of threshing is finished, no opportunity is left for the grain being pilfered or injured. The granary in this situation has not only the advantage of the ventilation of the side walls, but it has also the benefit of the free air from the open cart-shed under it, which acts upon the grain through the joints of the floor. The cart-shed under the granary besides being beneficial to it for air is convenient, particularly where a farm is situated at a considerable distance from a market-town; or in the winter season when the carts require to be loaded on the evening preceding the market-day; as it can be some hours yoking (putting the horses in), and without moving the carts from under their cover, by

means of the trap-door in the centre passage of the granary: which

1171

- a. Feeding-barn.
- b. Potato-house.
- c. Cart-shed.
- d. Calf-byre.
- e. Stable-house stable, and double stall attached for a mare and foal.
- f. Common farm stable with hay and straw-chamber above.
- g. Feeding byre, with straw-chamber above.
- h. Byre for hay or straw.
- i. Turnip-shed straw-chamber over.
- j. Potato-house with upper floor.
- k. Thrashing machinery.
- l. Clean corn-room, unfurnished corn above.
- m. Horse-shed for thrashing-machinery.
- n. Pump for liquid manure tank.
- p. Cattle shed.
- q. Privy.
- r. Straw-yard.
- s. Cart-shed, with granary above, carried over the carriage entrance to the farmyard and communicating with the clean corn room.
- t. Beddy for men servants, with beds in the upper floor extending over the poultry-house.
- u. Poultry-house.
- v. Pig-sties.
- w. Water-house.
- x. Tank for liquid manure.
- y. Turnip-barn.
- z. Guttering over the drains leading to the liquid manure tank to prevent the sewage from the yard from choking up the drains.

passage must at all times be kept clear from grain. In the straw-house, a trap-door is placed over the straw-rack; and, when the lower part of the house is packed full, this trap-door can be shut, and the straw carried along the upper floor to the straw-chambers over the stable and feeding-byre. These apartments will contain the straw of two racks, which will enable the farmer to keep different kinds of straw under cover and in separate divisions. A door is placed opposite the passage which extends along the centre of the straw-yard for taking out straw for the cattle-sheds, cow byres &c. If at any time required; but in general these are supplied from the low straw house. The thrashing-machine is one of six horse-power and is impelled by horses but where water can be had, it is a great improvement, as the men may be employed thrashing, while the horses are resting, this is advantageous in a still greater degree at certain times, when the field operations exhaust all the horse power.

2348. The circular byre (p), which will contain ten head of cattle is by far the most commodious and convenient arrangement and, for a farm double this extent, the same form may be introduced, with equal advantage, by carrying the stalls wholly round the circle where the sheds are. The figure of the stalls, being broad behind, gives more space for the cattle when lying down; and, as a greater quantity of litter is requisite, more manure, of course, will be made: at the same time it admits from behind a more abundant supply of fresh air and has also the advantage of one large ventilator in the centre of the circle serving the whole. The ten head of cattle are put up in double stalls in pairs; they are bound up, one on each side of the partition which is made high enough to prevent the horned cattle from conching one another at the same time keeping the heads of each pair at such a distance apart, as to prevent them from injuring each other or eating each other's turnips. The heads, or cow-eyes, are fixed to upright iron rods about three quarters of an inch in diameter which are screwed together through the partitions. The lower part of the windows in the back wall of the byre are filled with lath-work, which can be

1172

opened to any degree for admitting air, or shut altogether at pleasure. The feeding-part, or openings which surround the feeding-chambers, have small doors hung with pulleys, lines, and weights, similar to those of a common window, which by moving upwards, do not interfere with, or occupy any part of the chamber. The wall of the heads of the cattle surrounding the feeding-chamber is built to the full height of the joints; which keeps the turnip barrow out of the view of the cattle, and does not obstruct the air

direction of them, while the man is in the act of feeding the other. This is important, as the greater cattle are least the better, quietness being, no doubt, essential to quick fattening.

2282. A convenient straw-chamber is obtained over the byre, in a connected range with the straw or

1173

a. Platform forming the upper part of the roof of the feeding-shed.  
b. Ventilators to the byre.

c. Ventilators to the stable.  
d. Inclined plane between turnip house.  
e. Racks for hay or corn.

Although the under racks appear the most natural for the horses to eat from, it is found that they do not eat the straw or hay so clean out of them, as they do out of the upper racks, but these under racks are the most convenient for the grass, as it should always be put in from the stall below without passing through the hay chamber, being in its damp state, very harmful to the wood floor above. Part of the three-shed stable is set apart for a mare and foal.

2283. The turnip-shed (i) adjoining the feeding byre, is also conveniently situated for supplying the cattle in the straw-yard, and, as it is not required for turnips in summer it may be used for and serve the double purpose of a turnip-house and a grass-house.

2284. Ventilators. The cow byres have ventilators placed over each line of heads, these cross the ridge, and are formed of lead of a triangular figure the all pieces being overlapped by the sides far enough to prevent the rain from getting in. (See c in fig. 1173.)

2285. The calf-house and ward, and the cow-byres (c d), which fall under the class of offices more immediately connected with the farm-house have doors facing the kitchen-court which makes the access to them convenient and clean. The opposite doors are used for driving out the cattle, and for wheeling the manure into the straw yard. The outerward court, in front of the byres, besides being convenient for carting in the turnips affords space for the cows to move about in, or to stand in for a short time; and, as the cattle always dung when they are driven out, by allowing them to remain for a few minutes in this passage or court, the manure, that might otherwise be wasted on the roads, is preserved, and thrown into the straw yard.

2286. The several drains leading from the byres, stables, and straw yard, have such facilities as are sufficient to discharge the liquid manure into the tank which is constructed on one side of the straw yard in a central situation for the byres, stables, &c. It is thirty feet long, three feet broad, and seven feet deep; and, if the nature of the soil be porous, it should be plastered with Roman cement, to prevent the thin liquid manure from seeping. Being of this long and narrow figure, the tank can easily be covered with flagstones, which are much cheaper than arching, and take up less space. The drains should have holes fixed with cast-iron plugs placed about fifteen feet apart; so that at these openings a jointed rod fifteen feet long could be put into the drain, with a hoe, or a piece of plug from the shape of the drain, fixed to the end and of it. By these means the drains may be cleaned without breaking up any part of the passeway; but, if the drains are properly constructed, they will not require cleaning for several years. They should have a fall, towards the tank, of at least four inches to the ten feet, and be nine inches wide, six inches deep at the sides, and nine inches in the centre. By having this kind of triangular bottom the smallest quantity makes a current, and forces everything along with it. The drains through the straw yard should have openings with gratings (e f) over them, situated in the lowest part of the straw yard to draw off the surplus water after heavy falls of rain or snow. When these drains are not required, the gratings may be easily covered over with dung; and if, at any time, the manure is found too dry, movable apertures may be attached to the pump which is placed in the tank by which means the liquid manure can be regularly spread over the whole straw yard. A waste drain extends from the tank to an open ditch near the buildings; by which means, the liquid manure in the tank if neglected, is carried off when it rises to that level, and is thus prevented from injuring the drains.

2287. The cattle-sheds (g) from their situation, face the south, which is of great advantage to the cattle, though often overlooked in laying out farm buildings, and they are divided in the centre by a passage adjoining the turnip-shed, and opposite the straw-house. This passage rises like an inclined plane four feet from a to b; the sides or parapets may be of wood, two inches thick (which forms a back to the turnip-shed), and be four feet in height, forming a fence to both yards. All the manure from the feeding-byres and stables is wheeled into the straw yard by this passage, which from its central situation admits of the stable dung being equally distributed through both yards, and thus by the rising passage can be done without opening a door, which prevents the one class of cattle from intermingling with the other and getting out. Straw-stacks (A A A) are placed in the shade; but, by also having them in the centre

the roof, which is of considerable width, serving the double purpose of covering the feeding byre, and of containing a very large quantity of straw immediately over it. Racks are placed over the several stalls, which are filled from the straw-chamber above. By this arrangement, the cattle have it in their power to eat straw and turnips alternately if inclined. The access to the straw chambers over the byre and stables is by a stair which is common to both; and upon the plate (first landing-place) of this stair is placed a door which divides the stable from the feeding-byre; the upper flight of the stair is under doled to be a hanging one having a useful space under it for holding the byre implements. By the whole arrangement much labour in feeding and attending the cattle will be saved.

2288. The stabling (s s) consists of ten stalls, three of which are separated from the general farm stable, but are so situated as to admit of the racks being supplied from the general straw or hay chamber over the common farm stable. They are understood to have two sets of racks, the upper are for hay or straw and the under one for grass.

of the yard, and connected with this passage, they can be conveniently fixed, and the cattle are subjected to divide, which means the dung more generally through the yard.

8260 The pig-pen (v), from their situation, may be conveniently supplied from the kitchen or boiling-house, and are in both yards. Pigs are very beneficial to the manure, from their turning it over and mixing it; they also eat up any particles of corn among the horses' dung that may not have been digested. One small enclosure is provided with a trough for feeding young pigs and they are thus protected from the cattle while eating, but they have no house or sty. Cattle they may be induced to go out among the cattle, and to lie down about the stable. By this arrangement, they have healthy exercise, and are enabled at the same time to provide a part of their food, and to be beneficial to the manure in both yards. Another sty is provided for putting up a pair to feed.

8261 The gates to the straw-yard may either be of the common form, or be hung like sash windows, with stout ropes, pulleys, and weights. This last is perhaps the best plan, as it secures them from the risk of damage when the dung is being carted out of the yard; and also enables them to be raised as the straw in the yard rises.

8262 The water-house (w) is of such a height that pipes may be taken from it to the dwelling-house, hotting-house, calf-ward &c. It may be either supplied from a spring if one is to be found in the neighbourhood, or a well may be dug and a pump placed within the clover-house. A water-trough is placed in the division wall between the straw yards and a ball-cock is fixed in the centre of the said trough and shut in by boarding, overlapped by the upper part of the wall which thus protects it from injury by the cattle. By this self-acting supply the cattle at all times have the command of water and none of it is wasted. If supplied from a spring, no attention is necessary as the supply may be regulated by having a ball-cock in the cistern. Two troughs are placed on the outside for the horses and the milch cows, and are also supplied with ball-cocks. In the inside of the court is carried round with water-pipes, and with rain-water pipes at the south extremities leading it into drains. It is a material object to carry off the rain-water without allowing its admixture with the manure in the courts.

8259 Estimate —	Masonwork excavations and paving	s	d
	Carpenter's glazier's, and smith's work	578	0 0
	Plaster and plumber's work	470	0 0
	Plaster work	145	0 0
		5	0 0
		£1098 0 0	

The above estimate is made out upon the supposition that stone may be got for the working at a distance not exceeding one mile from the building, and that the land carriage of the timber (which is all foreign) and of the lime should not exceed from five to ten miles, and that of the slates from two to fifteen miles.

8263 —8276 *Wires or fence* strongly recommended as occupying less ground, and being ultimately cheaper than thorn fences. Quick in growth, hardly any of culture in all dry lightish soils, of unknown longevity prospering under the knife, affording in an evergreen a pleasing object to the eye, the best shelter for stock adapted for food and not suffering but rather benefiting from being cropped. Impressed with this conviction, W. Bell, Esq. of Humthill Roxburghshire planted this fence extensively and after a great number of years he is entirely satisfied with them (*Trans. H. S. vol. xi p. 411*).

8261 *Wire and netting fences*. An excellent substitute for hurdles or cords is manufactured of wire at Whittington, Stoke Ferry under the direction of Mr Taylor in the form of netting and sold at very low prices. Messrs Cottam and Hallen of London, also manufacture a cheap netting for sheep folding from cocoa nut fibre. Mr Taylor's wire netting is particularly valuable for rendering garden and poultry yard hedges impenetrable by rabbits, foxes &c.

8262 —8275 *Field gates*. The most advantageous forms and the lightest and cheapest materials are pointed out by Mr Baist, who recommends the ties or stays to be made of iron and the struts or stiffening pieces of wood. He recommends wire gates of a very light construction which cost from 1*l.* 8*s.* to 1*l.* 1*s.* These are figured and described in the *Gard. Mag.* vol. for 1840, p. 108 and in *Trans. H. S. vol. xiv p. 608*.

8263 —8104 *A fall down gate-stop* (fig. 1174) has lately been invented, which deserves adoption wherever double gates are fastened in the middle by a bolt attached to the lower bar and entering a hole in a stone or other body fixed in the road. This gate stopper is formed of cast iron, and is sunk in the ground till its upper surface is level with the road, its lower end being placed on a stone to prevent its sinking too deep. The gate-stop has an ear (a) which is raised up when the gate is shut, so as to form a stopper and a hole for the bolt and it is put down (b) when the gate is open, so as not to present an obstruction to the feet of horses. Sold by Messrs Cottam and Hallen.

## BOOK V

### THE OPERATIONS OF AGRICULTURE. (p. 506)

8284 —8289 The use of ploughing is for the purpose of loosening the texture of the soil so as to admit the free circulation of air and moisture in order to promote the decomposition or disintegration of the stony parts of the soil, and facilitate the extension of the roots of plants in it. However well you may manure your land however thoroughly you may drain it, you will never obtain the crops it is capable of yielding, unless you pulverise it. May, so important did Jethro Tull think this, that he felt strongly persuaded that if you pulverised your soil well you need not manure at all. Always bear in mind that the impalpable powder is the active part of soil, and that no other portion has any direct influence upon vegetation and you will then, at all times, be sufficiently impressed with the necessity of thorough ploughing harrowing &c. Indeed you may rest assured that, except upon some few very light sands, you cannot pulverise the soil too much. Secondary causes must fix the limit of this useful operation. Several chemical processes of considerable consequence as respects the fertility of soil, occur after it has been ploughed which either take place very slowly or not at all, while it lies undisturbed, and, moreover, some of these take place to the greatest advantage where. This is especially the case with the disintegration of mineral masses, nothing but the powerful action of the hardest stones to powder as sudden changes of temperature, combined with the presence of much moisture. During rain or thaw other new all the solids of earth and the

port of the more heavily aggregated stones becomes filled with water which, of course, freezes; the temperature is sufficiently reduced; and from its expansion during solidification a peculiar pressure is exerted in a vertical degree by water the particles of earth or stone, as the case may be, are pushed so far asunder that when the thaw returns, it crumbles into fragments, which are again and again acted on until reduced to the state of soil. This crumbling by frost is of the greatest importance in the case of stiff clays, for two reasons:—1st, because they are thus rendered much more easy to work; and 2d, which is of far greater consequence, they are enabled to give up their alkalies more readily to water; and silvery minerals are fortunately the quickest to disintegrate, or rather to decompose, by the action of the weather; and hence every means that facilitates that process is valuable, because, as we have already seen, those most valuable ingredients of soil, potash and soda, are of no use to plants, unless they are soluble in water and they do not obtain this property until the mineral with which they have been associated becomes completely decomposed. (Dr Madden in *Stephens's Book of the Horse*, vol. I. p. 341.)

8266.—8267. *Disadvantages of irregular ploughing*. As there is a certain stage in the progress of the grain, at which, when out, it produces more flour than any other that is, when it is full but not ripe, it follows that a field of corn which, in consequence of bad ploughing, does not come regularly into flower, must be attended with decided loss to the farmer. Those seeds which have been buried too deep will be the last to flower and consequently the last to ripen; so that, if he waits till the whole crop appears ready for the sickle, all the early seeds will be too ripe, by the time that the late ones are sufficiently dry to cut; so that by this error in ploughing there is a direct loss, by the production of less flour from the early seeds, while the farmer is waiting for the late ones to ripen. (*Trans. H. S.*, vol. xiv. p. 629.)

## PART III.

### AGRICULTURE AS PRACTISED IN BRITAIN

#### BOOK II.

##### GENERAL ARRANGEMENT OF LANDED ESTATES. (p. 558.)

8268.—8271. *A machine for cleaning public roads* described in *Q. J. A.*, vol. iv. p. 375. Another in *Trans. H. S.* vol. x. p. 349.

8267.—8269. *Keeping parish roads in repair* on the mile system. This system consists in putting "a certain portion or district of road under the sole care of one man, from which he is never removed so long as he conducts himself properly and that the materials, instead of being carted and laid on the road, at the time of repairing, should be contracted for so as to be brought and laid on the sides of the road and trimmed up in one uniform way ready to be measured up some months before they are wanted for use. (*Journal, A. E.*, vol. ii. p. 354.)

8269.—8247. *Shit ploughing*. Mr. Gorrie lays in all resinous plants, particularly larches, at an angle of 30° with the horizon, the tops pointing to the south-west, and finds this an effectual preventative to wind waving. (*Q. J. A.*, vol. xiii. p. 311.)

8269.—8260. *The perforator* (fig. 1175.) is used as a substitute for the spade, in planting young tap-rooted trees in rough ground. It was invented by Mr. Munro, of the Bristol Nursery and in that

neighbourhood, in 1838 cost about eight shillings. In using it, one man employs the instrument, while another man or boy holds a bundle of plants. The man first inserts the instrument in the soil, holding it up for the reception of the plant; round which when introduced he inserts the from three times, in order to loosen the soil about the roots; he then treads down the turf, and the plant becomes as firmly set in the ground as if it had been long planted. Two men may set from five hundred to six hundred plants in a day with this instrument. (*Gard. Mag.* vol. iii. p. 315.)

8270.—8267. *Pruning forest trees*. A digest of five essays on this subject, by Grigor, Gorrie, Cree, Fowle, and an anonymous author is given in *Trans. H. S.* vol. xli. p. 141.—179 which may be considered the most satisfactory article on the subject of pruning that has hitherto been published. All the writers agree in recommending a system corresponding with that of Mr. Cree's, but in some respects less definite.

8271.—8268. *Increasing the durability of timber*, by causing growing trees to absorb certain liquid solutions was tried by Dr. Beauchamp in France, and Mr. Hyett in England. (*Trans. H. S.* vol. xiv. p. 355.) The subject cannot be considered as yet settled: croceous and sulphate of copper appear to have been found most effectual preservative substances.

8271.—8268. *Mowing machines for felling timber* of four different kinds, will be found described in the *Highland Soc. Trans.*, vol. ix. p. 375. The most powerful of these appears to be a circular saw (fig. 1172.) which consists, first, of a ground frame (a c), in form of the common hand-saw, eight feet and a half in length by two feet and a half in width; on one side of which is erected a vertical frame (d b) of three feet and a half in height. The second compartment comprehends a traversing frame or carriage (e c) about five feet in length, and two feet in height; the vertical bar (d) being prolonged upward, and having its top and bottom ends turned into pivots, on which the carriage, carrying all the mowing machinery, is made to swing. The saw (f), of twenty-four inches diameter, is fixed on the lower end of a vertical spindle, and immediately above it a bevelled pulley (g), which is driven by the wheel (h); the wheel handle, by which the power is applied, is fixed upon the same spindle. The saw pulley and the

wheel (g) are in the proportion of one to five, so that, when the handle is turned with the ordinary velocity of forty revolutions a minute, the saw will make 800 revolutions in the same time. In order to keep

the edge of the saw in contact with the saw-draft a vertical spindle (h), carrying the pulley (f) of one foot in diameter is placed at the outward extremity of the carriage the pulley (g) is put in motion by the band (i) passing over a smaller pulley on the winch axle. On the spindle (h) there is also fixed a small drum (j), capable of being disengaged at pleasure from the motion of the spindle by means of a clutch. The cord (i), which passes round the pulley (m) in the ground frame, has one end attached to the carriage, while the other end, being attached to the drum is coiled upon it when revolving along with the spindle, thereby carrying forward the saw with a slow and uniform motion. When the operation is completed, the small drum is disengaged, and the cord is allowed to uncoil, while the carriage is moved backward to prepare for the next cut. For the support and guidance of the carriage an iron segment (n) is fixed upon the lower part, which slides through eyes in the ground frame and the machine is kept steady while at work, by two men dogs (grasping irons) the hooks of which are driven into the roots of the tree. The certificates accompanying the model of this machine bear ample testimony to its successful application on the large scale, and show that it can be worked, and carried from tree to tree, by two men. The machine here described is calculated for felling trees from eight to twelve inches in diameter. (*Highland Soc. Trans.*, vol. ix. p. 376.)

8373. *Species and varieties of the larch.* That extensively cultivated by the Duke of Athol is the common white larch *Lärch europæa* Dec; but the following other species or varieties were tried — 1. The Tyrol larch with white flowers those of the common variety being pink flowers. 2. The Tyrol larch, with white flowers the cones also remarkable for their whiteness and for being erect, not serotinous. The shoots of the Tyrol larch are generally stronger than those of the common larch; but the foliage of both kinds is similar. 3. The weeping Tyrol larch a variety of the common, with pendulous branches; but distinct in botanic characters from the *Lärch pendula*, or black larch of North America. 4. The red larch of North America or *Lärch microcarpa*. This species is remarkable for the great specific gravity of its wood which is so ponderous that it will scarcely swim in water. Its cones are shorter or smaller than those of the common larch its branches weaker and its leaves narrower. 5. The Russian larch, raised from seed procured by the Duke from Archangel, about the year 1806. The bark is obscurely not yellowish-brown the leaves come out so early that they are liable to be injured by spring frosts. The *Lärch pendula*, or black larch of North America, and *Lärch deatrica* of Dr Fischer of Petersburg, are distinct species, no examples of which exist at Dunkeld or Blair. (*North Trans.* vol. iv. p. 418.)

8374. As an Appendix to the chapter on Planting we shall here give some account of the larch plantation of Athol and Dunkeld, from the *Transactions of the Highland Society*, vol. xi. p. 185. p. 219. It appears that the late Duke of Athol planted 15,575 acres, which contained 37,481,500 plants of these 5,604,545 plants were larch. All these were planted in the slit manner as by far the best. It is stated in that paper that the larch will supply timber fit for ship-building, at a great height above the region of the oak and that, while a seventy four-gun ship would require the oak timber of seventy-five acres, it would not require more than the timber of ten acres of larch; the trees in both cases being sixty eight years old. The larch in the neighbourhood of Dunkeld grows at the height of 1800 feet above the level of the sea; the spruce at 1900 the Scotch pine at 700; and deciduous trees not higher than 500. The larch in comparison with the Scotch pine is found to produce three and three quarter times more timber and that timber of seven times more value. The larch, also, being a deciduous tree, instead of injuring the pasture under it, improves it. It is remarkable that the woody spire, which affected the larch plantations in most parts of Scotland for a number of years about the beginning of the present century never extended higher than about 600 feet above the level of the sea. The late Duke John the Second planted, in the last years of his life 4800 Scotch acres of mountain ground solely with the larch, which in the course of seventy-two years from the time of planting, will be a forest of timber fit for the building of the largest class of ships in his Majesty's navy. It will have been thinned out to about 400 trees per acre. Each tree will contain at the least fifty cubic feet, or one load of timber, which at the low price of 1s. per cubic foot, only one half of its present value, will give 3000s. per acre, or in all, a sum of 6,000,000s. sterling. Besides this, there will have been a return of 7s. per acre from the thinnings after deducting all expense of thinning and the original outlay of planting. Further still, the land on which the larch is planted is not worth above 9d. in 1s. per acre. After the thinnings of the first thirty years the larch will make it worth at least 10s. an acre, by the improvement of the pasture, upon which cattle can be kept summer and winter. (*Highland Soc. Trans.* vol. xi. p. 185.)

8375. *Soil for the larch.* It is an error to suppose that the larch will thrive in all soils and in all situations. There are many kinds of soils in which it will not thrive, and ought not to be planted. It has been found that, in soils which have been turned up by the plough, and which have turned white erose, the larch cannot. It cannot in wet situations also. In soils resting on a wet silty subsoil, it decays at the heart, after arriving at sixty years of age. In situations where water stands for a long time about the roots, it becomes fungoid, or covered with blisters. But in all rocky situations, and particularly those which are composed of mica slate, containing crystals of garnet, among the flowers and fragments

of which they can push down their roots, larches thrive to admiration. The peagmatic character of the country even demands in this is primitive. At Blair is gneiss; at Dunkeld, clay slate; and the intermediate space is occupied by mica slate; they lie conformably to one another.

3274. *Advantages.* The advantages resulting from planting mountain ground appear at first sight, in the greater number of trees that may be supported on the acidity of a mountain than on a surface equal to its base. Trees derive nourishment from the soil immediately around the place in which they are fixed; and, as the superficiality of that soil must, of course, be greater on an acidity than on the base, a greater number of trees will be there supported. Practically speaking, 100 trees, at six feet apart, can be planted on the hypotenuse of a right-angled triangle, whereas the base would only permit eighty at the same distance. Another and a great advantage derived from planting mountain ground is that, on an acidity the trees expose a greater surface to the influence of the sun and air and rain than they can do on a level surface. The trees derive much nourishment from the air through the instrumentality of their leaves there is no doubt. The experiment of taking the bark from fifty standing larches in May 1814, at Dunkeld, did not prevent their vegetation, and even forming wood for two years after. The outside trees in a forest are always the strongest. On an acidity, they all possess the advantages of outside trees; and at the same time, most of the shelter enjoyed by those in the interior" (*Highland Soc. Trans.*, vol. 185.)

3277. *Nurses* were not used by the late Duke in his larch plantation. The gardeners, in the Duke's absence, planted some acres with a mixture of Scotch pine and larch, but so far were the former from nursing the latter that at the end of seventeen years they had not attained a height exceeding three feet; while the larches which they were intended to nurse were from fifteen to twenty feet high.

3278. *The growth of the larch.* Taking the average height of an average larch, of eight years from the seed, at eleven feet, it will be nearly accurate to allow sixteen inches as the annual growth till the tree is fifty years old, and after that only ten inches per annum for twenty two years longer; as the length of the tree lessens in growth as the bulk of the wood increases. These data give a larch tree of seventy-two years of age a height of ninety-three feet four inches; a fair average, agreeing with actual experiment. The oldest of larches beyond the five years of age are heavier though they are not so long as those of younger trees. The larch, like the oak, puts forth two shoots every year, the one in spring, the other in autumn. The spring shoot has no lateral branches, the autumnal shoot pushes out like the spring one; but, at the time this process is going on the spring one is throwing out lateral branches which are firm and woody.

3279. *In regard to the growth of the growth a larch tree, on an average, will acquire an inch in girth per annum, till it be twenty four years old; and from that time, till it has acquired the venerable age of seventy-two years, it will grow one inch and a quarter in girth every year. Thus—*

*In 24 years it will be 2 feet in girth, at 1 inch per annum  
48 years thence, 6 feet in girth, at 1½ inch per annum*

*In 72 years, it will be 7 feet.*

3280. *The larch begins to make wood at twenty-four years of age,*

*At 50 years old it will contain 26 cubic feet of wood.*

*50 ————— 14 ditto more.*

*72 ————— 20 ditto more.*

*In all 60 ditto, or one load of 80 cubic feet, and 10 feet more.*

3281. *These results correspond exactly with the quantities which the Duke obtained at these respective ages. Larch appears to be on its greatest increase for timber from fifty-seven to seventy two years old. A larch containing fifty cubic feet or one load of timber is quite fit for naval purposes. At half that size it is suitable for every country purpose.*

3282. *Thinning larch plantations.* The great object of the Duke, in planting the larch, seems to have been to raise timber for naval purposes; and, finding that larches grow to a great size at only twelve feet apart, he thinned accordingly. This distance gives 250 trees to the Scotch acre, or about one fifth of the 2500 originally planted. The first thinning should consist of a light one of about one fifth of the whole, by removing only those trees that are of least value or worthless. After twenty four years from the time of planting, the spaces fall off the lower branches, which are, of course, no longer useful to the soil below. From twenty to thirty years old, then, the thinning is carried on so extensively as to remove two thirds of that which was left standing by the first thinning. In thinning it is necessary to observe that all the strongest and most useful trees should be left, even if two or three of them should be closer together than twelve feet. These small clumps happening to light on a favourable situation they will thrive well, as the air has access to each tree, around two thirds of its circumference. This thinning being delayed so long, the trees thinned out will be valuable for a variety of purposes. One of these purposes is the profitable use which may be made of the bark. The last thinning should be given when the trees are from thirty to thirty five years old, which will leave from 260 to 400 trees per acre.

3283. *Pruning the larch.* Little or no pruning was used in the larch plantations at Dunkeld. The 250 trees left in the acre, it is observed "will require a little pruning and trimming of the lower branches in order to give head room to the cattle, which are to browse on the grass below. The whole prunings and thinnings will cost about 1/2 and their produce will fetch about 1/2 leaving a profit on them of about 7s. an acre" (*Highland Soc. Trans.*, vol. xi p. 191.)

3284. *Then planting the larch is recommended by the late Duke of Athol because it allows the lower branches to extend to a greater size, and on these depend the thickness of the base of the trunk of the tree and the strength of its roots. He therefore seldom planted more than 3000 plants per acre, more especially in elevated regions.*

3285. *The process of the thinning of the soil, and the improvement of the pasture by the larch, being very important in its results, it deserves to be particularly described. The lower and stronger branches must together in six or seven years after planting so as to form a complete matting over the ground. The air and light being excluded by them, all plants that are under them die. At the same time, the annual deposit of leaves from them, by means of decomposition forms, in the course of time, a soil of considerable depth. At the age of twenty-four the larches lose the spaces on the lower branches altogether, and that in the natural result of their being ready to be removed by thinning, to a considerable extent. On the air being rendered by the removal of the trees, the surface of the new-made soil, wherever it has been formed, even among the rocks, becomes immediately covered with natural grasses, of which the *Elymus scabris* and *S. lanatus* seem to predominate. These grasses continue to grow and to thicken into a sward, by the annual top-dressing which they receive from a continued deposition of leaves. The improvement of the natural surface of the ground for pasture, by means of the larch, appears to be a property peculiar to this tree. This pasturage is quite capable of improving the condition of cattle, either in winter or summer.*

3286. *With regard to other trees effecting a change of the ground, the following are the results of many experiments made by the Duke on the subject. In oak copes, the value of the pasture is only 1s. or 2s. per acre for eight years only in every twenty-four years, when the cope is cut down again. Under a Scotch fir plantation, the grass is not worth 1d. more per acre than it was before it was planted. Under a birch and spruce it is worth 1s. than it was before, but the spruce affords excellent shelter to cattle, either from the heat of summer or the cold of winter. Under ash the value may be 2s. or 3s. per acre more than it was in its natural state. But under larch, where the ground was not worth 1s. per acre, the pasture is worth from 1s. to 10s. per acre, after the first thirty years, when all the thinnings have*

been completed, and the trees left for naval purposes, at the rate of about 400 to the acre, and twelve feet apart. May so impressed was the Duke of the value of larch as an improver of natural pasturage that he makes a statement to show that the pasture alone, independent of the ship-timber on it, would increase the value of land, by increasing its annual rental, so that it itself would repay the whole outlay of fencing and planting, at five per cent. compound interest, thus:—

3000 acres of land in its natural state, not worth above 1s. per acre, at 25 years' purchase	£	s.	d.
will give	1,750	0	0
Plants and planting at 6s. per acre	900	0	0
2400/roods of fencing at 5s. per acre	600	0	0
Sundry expenses, at 2d. per acre	37	10	0
	£75,567	10	0

89871 10s. at five per cent. compound interest, for twenty nine years, the period at which the land is fit to be begun to be depastured gives 21 1800. But 2000 acres at an improved rent only of 6s. per acre per annum, at twenty five years purchase, yield 10,500 (£Highland Soc. Trans., vol. xi. p. 156)

8987 The value of larch wood exclusive of the value of the pasture under it, may be estimated in this manner.—Suppose the plantations are thinned out by thirty years to what they are to stand for ship-timber—that is, to 400 trees per Scotch acre.—suppose, after that period, the whole were cut down at the following respective ages—the value of the whole, per acre, at the different periods, would be as follows:—

400 trees at 20 years old, at 2½ cubic feet each tree, = 1000 cubic feet, or 20 loads at	£
1s. 6d. per foot profit =	75 per acre,
400 trees at 44 years old, at 16 cubic feet each tree, = 6400 cubic feet, or 128 loads	450 —
at 1s. 6d. per foot profit, =	
400 trees at 60 years old, at 40 cubic feet each tree, = 16 000 cubic feet, or 320 loads	2000 —
at 1s. 6d. per foot profit =	
400 trees at 78 years old, at 60 cubic feet each tree = 24,000 cubic feet, or 480 loads	3000 —
at 1s. 6d. per foot profit =	

The average of these prices would be 1801/ 5s. per acre; so that 1000/ per acre is not too high a calculation of the value of the Duke's larch plantations

8988 On felling large trees of larch care must be taken to use plenty of rope and to take advantage of the direction of the wind, but a very windy day should be avoided. It was found in digging the Scotch fir cut by the roots from among the larch that the ground was so much shaken about the roots of the larch as to endanger their stability ever after the fir was cut over by the ground

8989 The seasoning of larch timber is accelerated by stripping off the bark before felling. In May 1815, the Duke experimented on fifty trees of larch at Dunkeld, that were growing in a situation among other wood that was nearly inaccessible for want of a road or path to it. In 1816 they were cut down and used for several purposes and they appeared to be completely seasoned. They contained twenty five cubic feet of wood each. Larch trees that had been only ten months cut down were built into a steam boat in the river Thames, but they had not been seasoned enough as the planks above water soon the deck shrank a little. In this case, however the soundings were made like some of oak which were of too slight dimensions for larch

8990 Uses of the larch. These are very various. Larches have been grown by the Duke as nurseries to spruce fir. The thinnings of larch plantations which take place from twenty to thirty years of their age supply useful materials for various purposes. Posts and rails for fencing may be made either out of the tops or the trunks of young trees. While fir posts and rails last only about five years, and are worn-out after that period, the larch-posts stand for twenty years and never get worn eaten. But the trunks of young trees are preferable for this purpose to the tops as they have less sap-wood. In 1807 the Duke fenced a nursery ground with young larch trees cut up the middle made into a railing seven feet high. In three years after the sawn side assumed a leaden grey colour and in 1817 the whole railing was quite sound. Larch tops which had lain cut for four years and were of course well worn were found useful in filling drains where stones were at a distance, and they continued sound in them for many years. The larch was used for axles to different kinds of mills from 1795 to 1802, and up to 1817 they continued quite sound, though constantly in water

8991 For building too the larch is found equally desirable. In 1779 the Duke built the shooting box in Glenmil, called Forest Lodge the floors and joints of which were made of larch. The wood was under forty years old, and as an experiment, some of the doels were cut up narrow and others as broad as they could be wrought. In 1817 the narrow boards continued quite close together. After the bridge was shown over the Tay at Dunkeld, the Duke altered the course of the great northern road to Inverness which caused him to build a new porter's lodge stables and offices at Dunkeld House near the new line of road. The whole wood work of these buildings was executed with larch. They were finished in 1812. In 1812 part of Athol House was burnt down and the repairs of wood, consisting of joists, floors, doors, and windows were all made of larch. This wood was so red in colour that it looked like cedar. Several houses were also repaired in the town of Dunkeld with larch. At Dunkeld 271 and at Blair 170, larch trees had been used by 1817 for building purposes

8992 The first attempt to use the larch for the purposes of navigation was in the construction of fishing-boats on the Tay in 1777. In 1809 8481 cubic feet of larch timber were sent to Woolwich dockyard. The greatest quantity which was employed was in the repair of the *Serpent* store-ship and the masts of its succedent was fearnably reported on in 1817. One beam of it was put into the large frigate *Shelley* in 1816, after it had lain six years in the dockyard. The next trial of larch in shipbuilding was in the *Sis Simon* Clerk merchant vessel, of 518 tons register, built by Messrs Gyles and Co. of Leith in 1810. They got eleven trees, containing 1006 cubic feet, and they were formed into the first four or five planks, of three inches and a half in thickness on the bottom of the vessel from the keel upwards. This vessel was soon afterwards taken by the Americans, and no account could therefore be got regarding the durability of the timber

8993 The elasticity, durability, strength, and resilience of larch timber, relatively to oak and Baltic fir has been determined by experiment. The details, in a tabular form will be found in the article quoted and the following are the general results.—The Rigatimber and American white pine are about one fifth part less strong than the larch. The larch is superior to the oak in stiffness, in strength, and in resilience, or the power of resisting a body in motion and it is inferior to Mamel or Rigatimber in stiffness only. The larch tree while growing may be sprouted by wind, but it seldom breaks over by the stem either by wind, or a weight of snow lodging on its upper branches. The durability of the timber in every stage of its growth is superior to every other even to oak itself. When speaking of all the above properties as belonging to the larch it is always to be understood to be grown in an alpine region, on dry soil. In low rich soils the wood is of a very inferior character

8994 The large roots of larch trees fit for ship timber may be used as knees and this was first done at Leith in 1811. These roots have been used for the same purpose on various occasions since that time

8995 The larch has been tried for masts but the vessels which were fitted up with them having left the Tay it is uncertain how far larch timber will answer for that purpose. It was the Duke's practice to plant spruce in all the wet parts of the ground, which he planted to the amount of about one-eighth acre for the purpose of raising masts and spars, for which he conceived the spruce particularly well adapted

**1835. The larch as a pine.** Two hundred and twenty-three trees, sixty-two years old, were converted into pine, and driven into the river Thames in the front of the works of the *Woolwich dockyard* in the year 1815. A report on their sale was made in 1817 when they were found to be as fresh as when they were driven in. It is impossible to picture this power without being strongly impressed with the sublime views entertained by John, the second Duke of Athol. Living in a period when the country was involved in a war with almost all other countries, he dreaded, in common with other patriots and statesmen, a scarcity of timber for naval purposes, and he contemplated the idea of planting so extensively as to provide against this scarcity for centuries to come. In all his plans and operations we see little or nothing of the narrow selfish principle at work. His great object was to provide a regular yearly supply of ship timber, the commencement of which supply could not take place till many years after he was dead. The following table shows the Duke's own calculation of the supply which would be afforded by the woods of Athol, from 1825 to 1864

15 years cutting from 1825 to 1844 will give	1,380 loads annually from	50 acres
10 — 1844 1854 —	8,000 —	308
5 — 1854 1864 —	18,000 —	680
5 — 1864 1870 —	30,000 —	1080
10 — 1870 1880 —	85,000 —	3000
10 — 1880 1890 —	180,000 —	3000

**1837. The relative duration of timber** has been thus determined by M. Hartig, an eminent German, professor of forestry. Small portions of lime tree, black, trembling poplar, planted in the soil, decayed in three years; the common willow, horse-chestnut, and the platinum in four years; the purple beech and the common birch in five years; the elm, the hornbeam, the ash, and the Lombardy poplar in seven years; the acacia, the oak, the Scotch pine, the Weymouth pine, and the spruce fir at the end of seven years were only decayed a little to the depth of a quarter of an inch; the larch, the common juniper, the Virginian juniper, and the arbutus were at the end of the same period, untouched by decay. Thin boards of the same woods in the following order: platinum, horse-chestnut, lime tree, poplar, birch, purple beech, hornbeam, alder, ash, the maple, the spruce fir, the Scotch pine, the elm, the Weymouth pine, the acacia, the oak, and the larch (*L. Agrostis* tom i. p. 215.) It thus appears that the larch, whether as posts with the bark on, or sawn up into boards, is by far the most durable of our timber trees.

### BOOK III

#### IMPROVING THE CULTURABLE LANDS OF AN ESTATE. (p. 690.)

**1836.—4213. Draining by steam power.** The application of steam power to the draining of land which the ordinary means of draining are insufficient to accomplish is among the most important improvements of the time. Land which, otherwise, could not be cultivated, or with the uncertainty of reaping what was sown, is now cultivated with profit and certainty. Beyond the localities in which steam power draining is in operation, little is known of it. In the *British Farmer's Magazine* for 1839 and also in the *Transactions of the Society of Arts* of that year will be found a detailed account of the steam power draining which has lately been effected in Cambridgeshire and Lancashire. It will be found of the greatest interest to those possessing similar tracts of land. The water is lifted with wheels, and raised about 2½ feet higher than the surface, at which height it flows off to the rivers or into draining order, plateaus, horse-chestnut, lime tree, poplar, birch, purple beech, hornbeam, alder, ash, the maple, the spruce fir, the Scotch pine, the elm, the Weymouth pine, the acacia, the oak, and the larch (*L. Agrostis* tom i. p. 215.) It thus appears that the larch, whether as posts with the bark on, or sawn up into boards, is by far the most durable of our timber trees.

**1838.—4267. The frequent drain system.** The great importance of thorough drainage, and deep ploughing, has lately been placed in a striking point of view by James Smith Esq. of Deanston in Stirling-shire, in an article contained in a *Report of the Exhibition of Agricultural Productions* &c. published in 1853, by Messrs. Drummond, seedmen, of Stirling. Mr. Smith observes, "that the practical drainers of the old school cannot see how a field should be drained, unless by deep cross drains, to cut off the springs. The portion of land, however, wasted by water springing from below, bears but a very small proportion to that which is in a wet state from the retention of the water which falls upon the surface in the state of rain, and a vast extent of the arable land of Scotland and England, generally esteemed dry is yet so far injured by the tardy and imperfect escape of the water especially in winter and during long periods of wet weather in summer, that the working of it is often difficult and precarious, and its fertility is much below what would uniformly exist under a state of thorough dryness. A system of drainage, therefore, generally applicable, and effecting complete and uniform drainage, is of the utmost importance to the agricultural interests, and, through them, to all the other interests of the country. By the system here recommended, this is attained, whilst the expense is moderate, and the permanency greater than on any other system yet known. The drains, as applied in the course have been named *wedge drains* from their form, and being filled with wedges or keys to preserve the opening in their bottoms. They are sometimes called *furrow drains* from their being placed under the water furrows of the ridges; but these terms give no expression of the principle upon which the effect of this mode of draining depends. The principle of the system is, the providing frequent opportunities for the water rising from below or falling on the surface, to pass freely and completely off, and, therefore, the most appropriate appellation for it is the *frequent drain system*."

**1850. Ridge drains.** In proceeding to apply this system of drainage to land, the first object is to obtain a sufficient fall, or level as it is commonly termed, for a main drain to receive the water flowing from the various smaller or ordinary drains. This drain should be directed along the bottom of the chief hollow or valley of the grounds where the whole or greater portion of the drains can be led into it. If any lesser hollows occur in the extent of surface, they must also have their proportional drains or leaders. The bottom of the main should be at least three feet; and, if possible, three feet and a half or four feet under the surface where it passes along; and it should have throughout as uniform a fall as the nature of the ground will admit. It should be dug at the bottom, or where flagstones are expensive, built as an inverted arch, to prevent the possibility of rain and washing away the earth under the side building. The dimensions necessary will depend on the fall or declivity and the area of land from which the drain has to receive water. With a fall in no place less than 100 yards, a drain ten inches wide, and eighteen inches deep, will receive the rain water from 100 acres. It is of great importance to make the openings of such drains narrow and high; as they will thus receive smaller bottoms and covers, and be less liable to give way; the current of water being also more confined, mud and sand will be less apt to settle in the hollow. Let the sides be smoothly and securely built with flat stones, either with or without mortar; and let strong the stones be placed over the drains; or, where such are not to be found, a rough sample arch, with thin stones and mortar may be built, packing the haunches of the arch well up to the sides of the cuts with earth beaten in closely. Where lesser hollows occur, crossing the fields it is necessary to cut sub-drains along their bottoms, about three feet or three and a half feet deep, and having openings of suitable dimensions formed by stone columns (two feet square placed together at the top and apart at the bottom, like the two sides of a triangle), or with double stones; or, where a very large flow of water has to be provided for with inverted tiles, and covering this placed above the bottom one, or with larger tiles made on purpose.

**8301. Submain drains.** There should be a cross submain at the bottom of every field or stretch of drains, to receive the water from all the parallel drains, and such submain drains should always be cut six inches deeper than the drains running into it, that the water may have a free drop, which will prevent the lodgment of mud or sand at their junctions or mouths. Open cuts or ditches, either as mains or sub-mains, should never, except from necessity, be adopted, being apt to get filled with mud and grass by which the water is thrown back into the drains and often chokes them, besides the loss of land annoyance in ploughing, constant expense of cleaning, and unsightly appearance of such drains, are serious objections.

**8302 Parallel or frequent drains.** Having thus provided a main drain, with submains flowing into it, matters are prepared for setting off and for executing parallel or frequent drains in the field. These drains can be executed at any season when the weather will permit, but spring and summer are most suitable for the work. It is best to execute the drains when the field is in grass, as they can then be cut in all kinds of weather, and in a more cleanly manner.

**8303 In setting out the drains,** the first object for consideration is, the nature of the subsoil. If it consists of a stiff strong clay, or a dead sandy clay then the distance from drain to drain should not exceed from ten to fifteen feet, but if there is a lighter and more porous subsoil a distance of from eighteen to twenty four feet will be close enough. When the ridges of the field have been formerly much raised it suits very well to run a drain up every furrow which saves some depth of cutting. At whatever distances the drains are placed they should be run parallel to the ridges which is commonly in the steepest descent. They should always be run quite parallel to each other, and at regular distances, and should be carried throughout the whole field without reference to the wet or dry appearance of portions of the field, as uniform and complete dryness is the object and land, which may be considered dry in its natural state, will show wet when compared with properly drained land. A three feet drain should be carried along the ends of these drains at the top of the field and at a distance of about nine feet from the fence especially if it is a hedge fence. Such a drain is necessary for the growth of the hedge, but if made nearer than nine feet the roots are apt to get into the drain and choke it up by degrees. It is of importance to be accurate in setting out the drains as described, as it secures uniformity of dryness, and in all future operations or at any time it is easy to ascertain the line of any drain.

**8304 Excavation.** The lines of drains having been marked off in the field, the drainer begins by cutting with a spade on a line, then removing the first layer to the depth of a spittle of about thirteen or fourteen inches wide all along, another follows with a narrower and tapering spade made for the purpose, taking out another layer; and when picking becomes necessary a third man follows with a pick, and a fourth with a large scoop shovel to cast out the earth and a smaller scoop shovel is used to clean out the bottom, which should be cut as narrow as will allow the last drainer a footing generally about three or four inches. From two to two feet and a half from the surface are the best depths for such drains the latter always to be preferred. The bottom should be cut as straight and uniform as possible, so that the water may flow freely along at all places and it is better to cut a little deeper when there is any sudden rise of the surface than to follow it, and where sudden hollows occur the cutting may, on the same principle be less deep. Attention to this also admits of after straightening or levelling of the surface without injury to the drains. The workmen, in cutting should throw the earth to the right and left from each alternate drain as that allows the plough to go regularly and fully occupied *boutings* (a Scotch term for a rotation or traverse of the plough) in filling in the earth whilst each alternate ridge or space is left for getting in the stones free from the earth thrown out.

**8305 Filling.** The stones may either be laid down at intervals by the sides of the drains to be there broken, or, being broken in masses at some convenient spot, can be brought by the carts, ready to be filled in. No part of any drain should if possible be filled in till the whole line is cut out and inspected, but the sooner drains are filled after having been cut the better. Sometimes when there is much tendency of the sides to fall in it becomes necessary to fill in going along. Cutting at the end of summer, when there is little water in the soil, or in a dry season, saves much of this. In soft or sandy bottoms by cutting the drains to half the depth in the first instance and allowing them to remain in this state until the water has drained from the upper stratum of the soil, the lower part may be cut out with more safety from falling in. The stones covering the drains should not be filled in nearer to the surface than eighteen inches leaving sixteen inches free for deep ploughing.

**8306 Covering the stones.** The upper surface of the stones having been made straight and uniform the whole should be neatly and closely covered with thin turfs, cut from the adjoining surface, or brought from some suitable place. Strict attention to the correct execution of this operation is of the greatest importance as many drains are ruined at once from the running in of the loose earth. Thick turfs are objectionable from the difficulty of getting them to fit close. Straw, rushes, broom whin and other like material, are very objectionable affording no certain or uniform security and forming a receptacle for vermin. Peat may be used to advantage. Where the deepest ploughing has been executed, there should always remain a firm crust of earth undisturbed over the stones of the drain, and no surface water should ever have access to the free way of a drain by any direct opening but should find its way, by percolation or filtration through the subsoil and should always enter by the sides of the drains. For this purpose it may be of advantage to tread or beat down closely the first two inches of soil put over the turf, in order to form the permanent crust.

**8307 The cost of executing such drains** varies, of course according to circumstances the cutting cost (in 1832) from 1s 6d to 2s 6d per rood of thirty six yards according to the hardness of the subsoil, the stones, if collected on the adjoining fields, will cost from 1s to 1s 6d per rood the breaking from 8d to 1s per rood; about one and a half cubic yards of broken stones will fill a rood of a well cut drain, the putting in of the stones may be calculated to cost about 3d per rood and the turfing about 1d, the filling in of the earth over the stones with the plough will cost about 1d per rood. The whole cost, per rood of common drains, may be taken at 4s 8d, or, including a charge to cover proportion of main drains 5s.

**8308 The following table** exhibits the cost per Scotch acre of draining in this method at various distances between the drains, and as this method of draining forms a permanent improvement of the land it is presumed the proprietor should defray part of the expense. The table is constructed to show how much it will cost the landlord in money to do the cutting carrying and (when necessary) breaking of stones, filling in and turfing, and how much the horse-work, &c., which can be performed by the tenant, will cost, charged at the ordinary rates —

8300. *Remarks.* In cases where time or capital are wanting to complete the draining, each alternate drain may be executed in the first instance; and the remainder can be done the next time the field is to be broken up. After the drainage has been completed, a crop of oats may be taken from the field; and immediately after that crop is off the ground, the field should be gone thoroughly over with the subsoil plough, crossing the line of drains at right angles.

8310. *The subsoil plough* has been constructed on principles appearing the best fitted to break up the subsoil completely to a depth sufficient for most thorough cultivation, say fourteen to sixteen inches, allowing the active soil still to remain on the surface; to be of the easiest possible draught, in reference to the depth of furrow and firmness of the subsoil, and to have strength and massive weight sufficient to penetrate the hardest stratum, to resist the shocks from fast stones, and to throw out all stones under 200 lbs. in weight. All this has been accomplished, and practically proved, over an extent of at least 200 acres of various soils. This plough requires four good horses, an active ploughman, and a lad to drive the horses and manage them at the turnings. Six horses, yoked three and three abreast, may be necessary in some very stiff or stony soils. A common plough drawn by a pair, goes before the subsoil plough, throwing out a large open furrow of the active soil. The subsoil plough following, stirs up thoroughly and breaks the bottom, when the next furrow of the active soil is thrown over it, the stones brought to the surface by the subsoil plough being thrown aside, on the ploughed part of the land, by a boy or lad; and so on, till the whole field is gone over. The boy should carry a bag of wooden pins, that he may mark the site of the large fast stones which the plough cannot throw out, and which must afterwards be dug out with the pick, and, perhaps, blasted. This large plough is a sort of horse-pick, breaking up without raising to the surface the subsoil. Channels are thus regularly formed for the water to flow from all parts towards the drains. The atmospheric air being also by this means freely admitted to the subsoil, the most sterile and obdurate clay becomes gradually ameliorated, and the common plough may ever after be brought to a depth of from fourteen to sixteen inches without obstruction, and with the power of three horses yoked abreast, and managed with ease by the ploughman, without any person to drive. By being thus yoked together, and near the point of resistance, the horses have great power, and, the furrow turned over being broad in proportion, nearly as much ground will be gone over in a day, as with a plough and a half drawn by a pair of horses. The cost of subsoil ploughing an acre may be estimated at 30s., being one sixth of what a similar depth would cost with the spade, and, upon the whole, as effectually done. A subsoil plough with apparatus cost, in 1832 from 7l. to 8l.

8311. *The effect of this mode of draining and deep working on close-bottomed land* is quite wonderful. After one turn of green cropping, with the usual application of lime and dung, the formerly scanty sterile surface soil becomes a deep rich loam, carrying, without fail, crops of wheat and barley, producing from nine to twelve bolls per acre of wheat, and from eight to twelve of barley, the hay and pasture following being also very fine. When fields have been thus dried and worked, it is recommended to plough them at all times without ridges, or water furrows, preserving one uniform sheet of soil over the whole field. By this means every superficial inch is allowed to be productive. There is no carrying away of the surface by accumulated currents of water; and the water falling as rain, is left to percolate through the soil where it falls, thereby uniformly enriching the whole extent. There is a powerful process of nature much facilitated by complete draining and deep working, viz., the constant circulation of air to and from the bottom of the soil, produced by the constantly varying relative temperatures of the atmosphere and the earth. When heavy rain falls, the air is completely expelled from the interstices of the soil, the water taking its place. Also, when the rain has ceased to fall, the water gradually subsides to the level of the drains, or, at all events, to the level of the bottom of the subsoil that has been moved by the plough, and fresh air takes its place throughout the soil, thereby promoting doubly a chemical action vastly conducive to the decomposition of the soil and the manure it contains; and, of course, to the nourishment of plants. When land is uniformly and completely dry and deep in the soil, it is more easily wrought. It can be wrought at any time when it does not rain; it comes to a state proper for sowing earlier, and more uniformly; a circumstance of great importance in our climate; it affords a wide and uninterrupted range for the roots of plants; it resists the evil effects of long droughts, as well as of long periods of wet; it never honeycombs, as it is called; it seldom throws out plants of any kind in frosts; it never suffers from the treading of cattle in removing the green crop; for, although apparently puddled or poached on the surface, yet, being dry below, a single ploughing restores the soil to a proper tilth; and it gives an earlier harvest, and affords a dry bed for cattle when in pasture. In the conclusion of his article, Mr. Smith observes, that the subject of thorough under-draining, and of deep ploughing, is one of so much importance, and so extensive in its parts, that volumes might be written on it to the advantage of the country. (*Report of Drummond's Agricultural Exhibition, &c.*)

8312.—4267. *Thorough draining* has been practised in Suffolk for many years; a narrow gutter being cut in the bottom of the drain, which is not filled up with any material through which the water drains in the usual manner, but with such materials as will support the earth above till an arch is formed; by which time the supporting material is for the most part perished, and a clear channel for the water left. The materials used are haulm, heath, a coarse rope of straw or of hop-blades. The practice is exceedingly well described in *Journ. A. B.* vol. iv. p. 23.

8313. *The direction of frequent drains with reference to the inclination of the ground*, is a subject on which at one time there was some difference of opinion. Deep drains to cut off springs are unquestionably most effective when carried across a declivity; but drains made in the furrows to carry off surface

water, will best attain their object when made straight up and down the slope. The reason is thus given by Mr Smith of Deanston. "Drains drawn across a steep, cut the strata or layers of subsoil transversely, and as the stratification generally lies in sheets at an angle to the surface, the water passing in or between the strata, immediately below the bottom of one drain, nearly comes to the surface before reaching the next lower drain. But as water seeks the lowest level in all directions, if the strata be cut longitudinally by a drain directed down the steep, the bottom of which cuts each stratum to the same distance from the surface, the water will flow into the drain at the intersecting point of each sheet or layer, on a level with the bottom of the drain, leaving one uniform depth of dry soil" (*Remarks on Thorough Draining*, p. 9.)

8314 *Tile draining* has the great advantage of suiting every soil, from the poorest to the richest, and of being used at any depth and where stones cannot be applied as in morasses or flour moat. It is less expensive than stone draining, and equally if not more, durable for if a tile should give way, it can easily be replaced, or a whole drain reopened and renewed at pleasure, which is impracticable with stones. Besides, being more portable, tiles can always be had of any size, shape or strength desired in those clayey districts where stones are with difficulty procured and may therefore safely be taken as the best substitute for stones in ordinary draining. Shut up from the influence of the weather, and secured from every injury it is impossible to limit their duration or conceive anything better calculated for the purpose of draining. In all cases where the bottom of the drain has very little slope tiles are decidedly preferable to stones, and ought, therefore to be used in such situations, even though they should prove more expensive than stones (*Trans H S* vol xii p 81)

8315. *Concrete drain tiles*, have been made by Lord James Hay and the mode of operation is most distinctly described and illustrated by figures in the *Trans H S*, vol xiv p 592. It can only be attempted with any prospect of success where there is strong quick setting lime and sharp sand. Perhaps peat may be advantageously compressed into draining tiles.

8316 *Peat cut like draining tiles* by means of a peculiar spade and dried in the sun during summer, and stacked like peats ready for use, is found an excellent substitute for clay tiles (*Q J A*, vol vii p 346.)

8317 *The substitution of larch-wood tubes for drain tiles* has been adopted by W Scott Esq Craigmoir, Kirkcudbright. The tubes are 4 inches square externally, with a clear water way of 2 inches. They are put together with wooden pins or nails as may be found most economical (*Trans H S*, vol xiv p 104.)

8318.—4330. *A tide sluice*, invented by the Rev George Cruden, is represented in figs 1177 and 1178, the first a vertical profile with the cover removed, and the second a vertical section, the same letters applying to both figures.

1177

1178

*a* the spout of the apparatus laid in the embankment, constructed of wood

*b*, the descending nozzle of the spout in which is placed the float valve also made of wood

*c*, the float valve being a hollow wooden box capable of rising and falling in the nozzle *b* from its buoyancy in the tidal water, so as to shut or open the passage *a*

*d*, openings for the escape of the collected water which is discharged during the recess of the tide

The mode of the float's operation is thus: "During the recess of the tide the float by its own gravity descends until its upper surface is on a level with the sole of the spout, thus giving free egress to the fresh water collected in the reservoir until the flood tide has risen so high as to envelope the float in its water

The float is then raised by its buoyancy in the tidal water and so closes the passage through the spout *a*, preventing either the ingress of the tidal water or the egress of the drained water until the tide has again fallen below the level of the float. Perhaps a more uniform and more permanent action would be obtained by constructing the float, and the chamber in which it operates, of thin sheet copper, or of sheet iron, and giving it a cylindrical, instead of a cubical form" (*Trans High Soc*, vol xli p 137.)

8319.—4406 *Sluices, trunks, and valves for embankments* are now made of cast iron, on an improved principle, and, when properly fixed in by a mass of masonry and cement, they are found to retain the water of a pond, and admit it at pleasure, with as much accuracy and ease as a brass cock does the contents of a beer barrel

8320.—4485 *Artesian wells*, or those produced by boring are so named from their having been first used in the neighbourhood of Artes in France. Upon a review of the appearances observed in these wells it is quite evident that they must always succeed where an inclined stratum of a fissured or porous limestone or other porous stone is included between two waterproof beds of clay, one of which acts a limit to the sinking of the water downwards, and the other prevents it from rising above the surface. The existence of such a cover is evinced by all boring works. A waterproof stratum of clay must always be penetrated, before reaching the spring water, and it may easily be conceived that the undermost layer is never wanting. Although, for the most part, some thinner strata of limestone supply its place, yet the strata, which conduct the water, always contain it in crevices, which are much more numerous on the surface than in the centre of the beds. Thus there is a demonstration, as in a boring work at Biengel, that, even in the limestone itself beds of clay occur. From these circumstances it is easily explained how we can never hope to sink Artesian wells in granite, gneiss, porphyry, serpentine, &c. Even in schistose mountains, it would not be advisable to sink these wells, because, if water were found there, it would be very easily impregnated with sulphuretted hydrogen, from the abundance of pyrites occurring in these strata and thus be unfitted for many uses. Limestone, on the contrary which is very insoluble experience teaches us, yields a very pure water. These observations especially relate to the Pas de Calais

8321 *Other districts* where water has been bored for show a similar geognostic constitution to the Pas de Calais. M Garmer, in his *Manuel du Pontanier-sondeur*, &c. notices this, with regard to Boston in America, and Sheerness in England. London (where many sugar-works, distilleries, and breweries have for a long time been principally supplied with water from Artesian wells) lies in the middle of a basin-shaped hollow, the fundamental rock of which is a limestone belonging to the chalk formation; which also forms the heights in the vicinity, and which is covered with clay though at times not immediately. The wells, which are not sunk to this London clay give abundance of clear, but mostly very hard, water, while those which penetrate through the London clay into the subjacent plastic clay, a formation immediately covering the chalk, and consisting of alternating beds of sand, clay, and boulders, yield a very soft and pure water, which, on piercing this clay, often ascends with such violence that the workmen have scarcely time to escape. Here the plastic clay seems to be either the conducting medium, or the reservoir of the water yielded by the chalk. Paris is known to be situated in a district whose geognostic relations are most identical with those of London, and therefore we cannot wonder that there, as well as in many other parts of the north and east of France, Artesian wells may everywhere be sunk, nor can we doubt of the extension of this very useful discovery (*Jameson's Phil Journ* for July, 1830.)

8322 *We must not, however, expect to be able to sink Artesian wells in every description of country*, as has been thoughtlessly asserted. On the one hand, the nature of the ground sometimes absolutely prevents it, as in granite districts; and on the other hand, it is possible that a perforation, if made too near

a bored well affording water, may not yield any; should the latter, for example, be fed by a subterranean current, in place of being supplied by a sheet of water; or should the perforation be made upon the extremity of a basin with inclined strata, resting upon a formation of a very different nature. M. Garnier's *Manuel des Fontainiers-sondeurs* contains all that can be desired on the subject of boring these wells. (*Ibid.*)

8335. *General observations on Artesian wells.* Great subterranean sheets of water exist at various depths. These sheets are more commonly met with in the plane of superposition of strata of different formations. They, however, frequently occur at various heights in the great masses of earth; such as those of clay, chalk, and even marine limestone containing corallia, when these masses are entire and of great thickness. According to the slope, the undulations, or the declivities which are presented by the plane of superposition of the permeable deposits in which the waters flow between impervious strata, these great sheets of water are met with at all depths; but it is impossible to lay down any constant rule with respect to them. (*Ibid.*)

8334. *In order that these waters may be capable of ascending,* it is necessary that the formations among which they occur be entire, in the state in which they were originally deposited; and that they be not intersected by large valleys, or deep ravines, through which the waters would find a free and easy exit.

8335. *It would be in vain to search for springs in deposits which, at no great distance from the place of boring, are intersected by deep valleys,* or when the formations are internally crooked, filled with tortuous separations, and greatly disturbed, whether by the contraction attending the desiccation of the mass, or by internal shocks, swellings, or earthquakes; or, lastly, when these Neptunian formations, such as plastic clay, chalk, oolite, and shell-limestone, are raised up, and present precipices at the surface. In such localities, we need not expect success in boring for springs, unless by penetrating deeply into the mass of the chalk, in search of the sheets of water in its lower part; or even by traversing it entirely, in order to come upon those in the clays, oolites, and shell-limestones; or, lastly, unless by penetrating deeply into the latter, when they happen to be raised to the surface, and to present cliffs, or are intersected by valleys of greater or less depth.

8336. *In a country composed of elevated plains,* if, in place of boring to the necessary depths for reaching the different water-sheets which are commonly the most abundant, and, at the same time, those which rise highest, the boring is stopped at higher levels, less distant from the surface, it is more than probable that the ascending waters will stop more or less beneath the surface of the ground, according to the depth of the borings. When this occurs, we ought to be far from considering the operation as having failed; because in this case the water does not rise above the surface, and in most instances, according to the localities and the nature of the ground, steps may be taken to remedy the deficiency. Thus, for example, when the water of a boring only rises to within a certain number of yards from the surface, but in sufficient quantity, it might be conducted from the point to which it reaches, by a small gallery, unto some neighbouring well, or into one dug on purpose; and there might thus be produced a kind of artificial fall, which might be employed to make the water ascend to the surface of the ground, and even beyond it, by employing for this purpose either the hydraulic ram (*bélier hydraulique*), which would always give a third of the volume of water, or a wheel, which might be placed at the point of the fall, and which, working a pump suitably placed, might raise the third, or perhaps even the half, of the volume of water; or, in short, any other hydraulic machine of the kind. But these means would be practicable only in so far as the wells into which the waters should be precipitated might not allow them to run off into strata of permeable deposits.

8337. *Circumstances which it is necessary to examine and appreciate before resolving upon boring a well.* It is necessary to examine the physical constitution or the nature of the ground, and the disposition of the surface of the country, with reference to the mountains which overlook it, the valleys by which it is intersected, and the springs which rise in those valleys. The latter it is particularly necessary to examine, before deciding upon boring a well, as many of them are natural wells. It is of importance to select a fit person for boring, the art not being merely mechanical, and such as can be practised by any borer. Besides attending to these circumstances, it is necessary to be possessed of perseverance and courage, which will lead us to disregard the delays and difficulties often unavoidably connected with the operations of boring. (*Hérart de Thury, as quoted in Jameson's Journal for July, 1830*)

8338. *Boring for water in deep sand.* Mr. David Greenley, of London has been lately (August, 1834) very successful in obtaining "an abundant supply of pure water," at Diss in Norfolk, at a depth of upwards of 600 feet below the surface. A well had been previously sunk in the same place; but, in consequence of an immense quantity of sand rising whenever the pump was worked, it was almost useless. (*See Arch. Mag., vol. i. p. 210.*)

8339. — 4512. *The improvement of waste lands,* whether moss, bog, or wet clay is exemplified in seventeen different cases reported on in the *Highland Society's Transactions*, vol. x. p. 281. The article embodies an immense amount of valuable practical information on the subject.

8340. — 4534. *Revdng rocks or stones.* A newly invented apparatus for this purpose has been brought into notice by Mr. D. Millar, road contractor and builder in Edinburgh. The apparatus appears to be a more efficient boring instrument than any hitherto in use. It is calculated to bore or tap to the depth of 100 feet or upwards, and may be put in operation either by manual labour or steam. (*Scottman, Feb. 22 1834.*) An instrument for the same purpose was invented by Mr. Mallet of Dublin in 1832. Mr. Mallet's object was to split all rocks that could be separated into laminae by the application of the male and female screws; instead of blasting, as heretofore practised, with gunpowder. The process is as follows: — Jumper noles are formed in the direction of the proposed fracture, as at present; but, instead of filling them with gunpowder, a split female screw is inserted in each hole, and the fracture is effected by the insertion of a conical or male screw. (*Arch. Mag., vol. i. p. 93.*)

8341. — 4541. *Drainage and bringing into cultivation moss-lands or peat-bogs.* The Liverpool Agricultural Society having awarded its premium to Mr. Reed, late of Chat Moss, but now a professional drainer, we give the following as the essence of his paper. We may premise that we had the pleasure of inspecting Mr. Reed's farm at Chat Moss, near Liverpool, in August, 1831, and were much gratified and instructed by what, when there, we saw and were told by Mr. Reed.

8342. *Drainage.* The water, to a considerable depth from the surface, being held in a great degree by capillary attraction, drains should be frequent, and more or less distant according to their depth. Open drains to divide the fields may be placed at any distance not exceeding 100 yards. The covered drains should run at right angles to the divisional drains. Sixty-six yards, or three chains, Mr. Reed has found the best width between the open drains; and, consequently, as the covered drains are at right angles to these, their length will be sixty-six yards. The open drains may be four feet wide at the top, from three feet six inches to four feet deep, and fourteen inches wide at the bottom. The covered drains should not be more than five or six yards apart, and three feet deep. No material is wanted to cover them but the moss itself. "The form should combine the principle both of the shoulder and the wedge drain, and the somewhat square cled, which is first taken out, when dried to a certain extent by the weather, becomes the cover."

8343. *Preparing the surface.* "Moss, or peat bog, is not a soil, but an accumulation of dead, dying, and living plants growing in water." To form a soil, therefore, it is necessary to destroy, to a certain depth, the original structure of the moss, both for the purpose of destroying vegetation, and facilitating the passage of the water to the covered drains. Digging is perhaps the best mode of destroying the structure of the moss, and afterwards, a cutting machine formed by fixing circular knives on the cylinder of a common roller, may be applied. In due time, the surface may be harrowed, and afterwards manured,

and sown with a crop. Any description of earth is useful, as tending to consolidate the moss, and to facilitate its decomposition; but, to obtain a good crop the first year, putrescent manure is a considerable quantity is absolutely necessary.

8334 *After cultivation* "Manure of some sort being applied, almost any description of crops may be had, but potatoes are perhaps the best article to begin with, 2d, wheat, 3d, clover, without grass seeds, 4th, oats. The rotation may be varied, so as to include almost every crop."

8335 *The preparation of coke or charcoal from peat or moss* has been effected in different parts of Scotland, and in Ireland, and the charcoal thus produced has been found superior to many kinds of coal for smelting iron, and the use of smiths' forges. This arises from the total absence of all sulphuric matter in the peat, which renders it almost equal to the charcoal of wood, to which it is well known the Swedish iron owes its principal excellence. The charring of peat for use in smelting iron has been strongly recommended as a means of giving employment to the labouring population (See *Brit Farm. Mag.*, vol v. p. 360.)

8336.—4962 *Ripening corn* It is important Dr. Madden observes that the process of ripening after the seed has filled, should be as rapid as possible. "When the ear first fills, it appears composed almost entirely of a substance resembling milk, in about a fortnight after this if we again examine the crop, we shall find the seed much more solid, the milky juice having hardened and consolidated, and the straw having begun to wither, which it always does from the ground to the ear. At this period the straw will be yellow for about a foot above the ground, in another fortnight the crop will be perfectly ripe, that is to say, the straw will be uniform yellow up to the ear, and the chaff will be sufficiently loose to admit of the grain being rubbed out by the hands. On examining the ear, the most perceptible difference which has taken place since the last period is, that the skin has become much thicker and harder, while the flour is diminished in quantity. Now this is the important point, viz, that the last change in the seed is an increase of bran, and a relative diminution of flour, which change increases materially according to the length of time that elapses between the ripening and the harvesting of the crop" (*Trans. H. S.*, vol xiv p. 628.)

8337.—4991 *Diseases of Corn* Professor Henslow delivered a learned lecture on this subject, the essence of which will be found in the *Gard. Chron.* 1841, p. 5

8338 *The bunt fungus (Uredo caries Dec)*, called also smutballs and pepperbrand, may be described as a powder occupying the interior of a grain of wheat, the only corn it attacks. The effects which alkaline substances, such as potash, lime &c., produce in destroying the smut, when seed or corn is dressed with those substances, is supposed to be owing to their forming a soapy compound with the oil of the fungi, which is then more easily detached from the surface of the corn, to which its natural greasiness makes it adhere.

8339 *The smut or dust-brand (Uredo segetum Dec)* is a fungus which differs from the last in wanting its disgusting odour, and in escaping through the sides of the infected grain in the form of a sooty powder. It rarely attacks wheat but is a common enemy of oats and barley. The usual palliative of this evil is steeping, as in the case of the bunt.

8340 *Rust (Uredo rubigo Dec)* is a fungus resembling an orange powder, exuding from the inner chaff-scales and forming yellow or brown spots and blotches on various parts of corn plants. In itself it is a pest of comparatively small importance, but Professor Henslow has made the very curious discovery that it is the young of the mildew, the *Puccinia graminum* of botanists, which is so destructive when it attacks the straw. He stated that these fungi are at first spherical, or nearly so and then constitute the *Uredo* or rust, but by degrees the spheres lengthen, acquire a stalk, contract in the middle, and so form the head of the *Puccinia*, so that two supposed genera of botanists, *Uredo* and *Puccinia*, are undoubtedly the same species in different states of development.

8341 *Ergot* was regarded as a monstrous state of the grain of rye, produced by the external action of a minute fungus, which causes the grain to lengthen into a horn something like a cocks spur. It is so exceedingly oily that it will burn like an almond in the flame of a candle. The action of ergotised corn has been ascertained to be highly deleterious, both to man and animals, the latter, indeed preferred starvation to feeding upon it, even when mixed with good flour. A duck which had been fed with ergot mixed with flour, in the proportion (say) of 1 in 17 died in ten days, after having had the end of its tongue rotted off, and drops of blackish blood oozing from its nostrils. A pig was poisoned in like manner in twenty three days, the ears and the flesh of the tail having rotted away, and the legs having mortified. Fortunately we know little of this pest in England, for it is equally fatal in its horrible effects upon man, as has been amply proved in France. Draining is considered as the only known preventive of ergot.

8342 *Ear cockles* are produced by an animalcule called the *Vedrio tritici*, which may be compared to the eels in paste on a small scale. They form a cottony mass in the interior of the grain which, when the latter is ground, will not pass through the cloth, but remain behind in the bran. Although this creature is microscopically small when young, it is a giant at its full growth becoming a quarter of an inch long. Nevertheless, Mr. Bauer has calculated that 50,000 of the young might be contained in one grain of wheat. Scalding water was mentioned as the most obvious remedy for these creatures.

8343 *The wheat midge (Cecidomyia tritici)* millions and millions of which infest every wheat-field, is hardly known by farmers to do them any wrong, and yet, on an average, it destroys one-twentieth of a crop, and may possibly destroy a great deal more. It appears in June, up to which time its chrysalis lies amongst the chaff of the corn. When the corn is winnowed, the pupæ of the midge are driven forward with the chaff from the winnowing machine, and fall before it within the space of about three yards. As wheat chaff is always sifted before it is given to horses, and the pupæ pass through the sieve with the dust, it occurred to Professor Henslow that if a wire gauze sieve were placed before the winnowing machine in a sloping position, so as to allow the chaff to fall upon it, and then roll from it the pupæ would pass through, and might be taken with the dust in a tray placed below the sieve (*Gard. Chron.* 1841, p. 5 52, 566 815.)

8344 *Cure for smut* Steep in dunghill water, to which salt and saltpetre, or copperas, have been added, so as to cause the water to bear an egg steep the corn twelve hours, and afterwards dry it with slaked lime or dry turf ashes, and sow it as soon as possible (*Gard. Chron.* 1841, p. 69.)

8345 *Smut* effectually cured by scalding in boiling water for a few seconds, and then dipping in cold water and drying with lime. Great care was taken that the water was boiling, and the wheat taken out of the water as soon as completely wetted. (*J. Ellis, Esq. of Barrow in Kent, at the February Meeting of the English Agricultural Society.*)

8346 *Sleeping seed wheat* Professor Henslow found that steeping in sulphate of copper effectually prevented disease, while it did not affect germination. (*Gard. Chron.* 1841, p. 815.)

8347.—4992 *The advantages of cutting corn crops before they are dead ripe*, that is, when the straw immediately below the ear is just beginning to turn yellow, are thus summed up by Mr. Sherriff.—An increased quantity of grain, greater security from the weather, improved quality of straw, and an extension of the harvesting season. To these may be added, greater security against the effects of wind and rain, either as affects the shedding, discoloration, or germinating of the grain. The colour of grain which was not cut till it became dead ripe is generally of an opaque whitish hue; while that which was cut before it was dead ripe is transparent, and tinged with brown. The latter description of sample bears the highest price in most British markets. (*Brit Farm. Mag.* vol v p. 23.)

8348. *The period at which corn crops ought to be reaped* is best determined by examining the upper grains of the spikes. The cereal grasses, like all monocotyledonous plants, ripen the seeds on the upper extremity of their flowers, or even in the upper part of their seed-vessels, in the case of plants with pods containing many seeds, whereas dicotyledonous plants ripen their seeds equally throughout the seed.

vessel, and in general rather ripen them first at the lower and than at the upper end. When the uppermost grain of a spike of corn has dropped out, the stalk may be considered as having stood rather too long, and the reaping point to be that when the uppermost grain is firm and plump. On the whole, the most improved practice of British farmers is in favour of reaping their crops at an earlier state of ripeness than they have hitherto been accustomed. (*Quart. Journ. Agr.*, vol. iv. p. 501.)

8349.—4998. *Cutting grain crops with a common scythe* has been generally practised in Aberdeenshire since 1818. The crops grown in this country are chiefly oats and barley. No change whatever is made in the common grass and clover scythe, for cutting heavy or lodged grain crops; but for light standing crops, a very simple addition is found of advantage. This consists of a small rod or shoot, nearly an inch in diameter, of green willow, or rowan (mountain ash), or broom, or any other flexible and tough young wood. It has its thick end twisted into the small iron rod, which aids in attaching the blade of the scythe to its handle, named provincially the grass-nail. Its small end passes over the upper side of the blade as far as the back, where it is bent upwards in an easy curve, and is brought backward, and tied with several rounds of strong twine to the handle, about fifteen inches above the blade. In cutting grain with a scythe, the swathe or cut corn is laid away from the standing corn. Every mower is attended by a gatherer; and, as the gathering is the part of the work that women can best perform, the gatherers are generally women. The grain is left by the scythe, having the stems forming an acute angle with the line of the standing corn, the root end of the stems pointing partly backwards and partly inwards towards the uncut part of the field. The gatherer places herself at the root end of the stems, so as to be able to stoop forward nearly in the line in which they are laid; and by a succession of lifts with her hands, placing the corn on the rear over that which is mown forward, stepping at the same time towards the right hand herself, she gathers into one heap what she deems sufficient for a sheaf, and, having carefully separated it with her right hand from the forward part of the swathe, then makes a band, in the ordinary way, of a part of the gathered heap, and lays the heap upon it. A binder is also attached to every mower, who is able to bind up all the sheaves cut by one scythe, and also to set them up in shocks, but there is no novelty in his operations. The gatherer and binder could generally, after a skilful mower, gather up all the corn sufficiently clean, but their labour would be greatly impeded, so as that they could not keep up with the scythe, were the cleanest gathering strictly enforced. That is, therefore, dispensed with; and a raker, generally a woman, follows the other operators, to collect the straggling ears and straws. (*Highland Soc. Trans.*, vol. x. p. 189.) The Rev James Farquharson, speaking of this mode of reaping, says,—"In no branch of agricultural labour not even in the substitution of the two horse plough for the one drawn by ten oxen, or of the threshing-machine for the flail, has a more valuable advance been made, within our memory, from an old and inferior system to a new and better one, than in the adoption of scythe-reaping. It is calculated that double the work is done by the scythe which could be performed in the same time by the sickle. It is also better performed; because the straw is cut off more closely to the ground, and consequently a better provision is made for cattle fodder during the winter, and for a larger quantity of manure. When the grain is over-ripe, much less is shaken out by the scythe than by the sickle. Another advantage, of which the magnitude can scarcely be believed, except by those who have learnt to estimate it by their own experience is the quickness with which the mowed shock wilms (drys or withers) thoroughly, and becomes fit for the stack, a matter of the utmost importance in our unsteady climate. The straws are not crushed, as they frequently are with the hand in reaping with the sickle; and the sheaf, although not more liable to break out of the band, is more elastic and open to the action of the atmosphere. It is perhaps not too much to say, that a sheaf of equal weight, cut with the scythe, becomes ready for the stack, under equal circumstances of weather, in half the time needed by one cut with the sickle. The most pleasing advantage is the total change of the character of the labour, as it affects the larger part of the workpeople. The mowers, gatherers, and rakers deem their work delightful in comparison with the labour of the sickle."

8350. *The scythe for reaping corn* (fig. 1179) should have its blade (a) of the best steel four feet long, strengthened by a plate of iron along the back (b). The handle should be straight, because that gives the greatest command over the scythe. A well-seasoned young larch tree, reduced to the proper thickness with a slight curve at the root end, for receiving the blade in a proper position, makes the best handle to a reaping-scythe. A hone covered with fine sand, and a fine sandstone, to whet the edge of the scythe are hooked on to the handle at c, near its upper extremity. There should be a cradle (d), consisting of three long teeth fastened to an upright stem (e), formed of ash, and as light as the strength of the wood will permit. The upper tooth should be a little more than two feet in length, and the two under ones should be, the first three inches, and the second six inches, shorter. The upright stem of the cradle is driven into a socket of iron. The height of the cradle is about thirteen inches, the left-hand handle (f) is straight, and the right-hand handle (g) is crook'd. For the construction of this important instrument, further details will be found in the *Quart. Journ. of Agr.*, from which our figure is taken, but the above outline will suffice for any one who can construct a common scythe.

8351. *Corn of every description may be reaped with the scythe.* Oats make the most perfect work, with the greatest ease to all the labourers. Barley, with new grass, is not difficult to cut; but the clammy juice from the barley straw lubricates the scythe with a viscid coating like varnish, which must be rubbed off frequently with the whetstone. The binders have always hard work among barley. Wheat is beautifully laid in swath when mown. The takers-up and binders have less labour among wheat than the mowers, who must be powerful men to continue a length of time at the work, but there are modes of equalising the labour, and, of course, of diminishing the fatigue. For example: when a

field of wheat and a field of oats are nearly ready for reaping it is an excellent arrangement to reap the oats in the dewy mornings, before breakfast, or as long as there is any dampness on the corn, and then to go to the wheat, or to the barley, if there be little wheat on the farm, during the dry period of the day. By this plan much valuable time can be saved in reaping the whole crop. Oats are not the worse for being reaped in a damp state. It is a remarkable fact, that oats reaped in a damp state, with the scythe, will be nearly as soon ready for the stack as when reaped dry. Not so with barley. Shocks of oats which are reaped dry, but have afterwards been soaked with rain, will be longer before they are ready for the stacks than oats that have been reaped in a damp state. It is a still more remarkable fact, that damp oats reaped with the scythe will be sooner ready for the stack than would the same oats, reaped in a dry state with the sickle. Oats reaped with the scythe will be quite ready for the stack in eight days, whereas oats reaped with the sickle require at least a fortnight. Shocks that have been reaped with the scythe will keep off much more rain than those reaped with the sickle. (*Quart. Journ.*, vol. iv. p. 366.)

8352.—5002. *Wheat* said to be indigenous in the country of the Baschkirs, where the summer temperature is as high as 97°. It is grown extensively in Egypt and Barbary, in the Caraccas, and in Cuba, in

places little elevated above the sea. Hence it may grow in the West Indies. The varieties cultivated in warm climates accommodate themselves to them. (*Gard. Chron.* 1841, p. 451.)

8353.—5003. *Cone wheat*, a variety of *Triticum turgidum*, has been found by Mr. Gorris to be but little injured by the wheat-fly, as this insect appears in the fly state much sooner than the wheat blossom bursts from the spike. The grain of this variety is coarse; but every spike generally yields from seventy to ninety grains, which is double the number of the common wheat, *Triticum hybernium*. It ripens about a week after the red wheat, and, when standing, is from a foot to eighteen inches taller than the common wheat. (*Quart. Jour. Agr.*, vol. iii. p. 641.)

8354. *Danzig creeping wheat* is a variety cultivated on the borders of Scotland, which possesses the property of tillering, or throwing tap-shoots from the root in the autumn, in a remarkable degree. It originally came from Danzig. (*Quart. Jour. Agr.*, vol. iv. p. 536.)

8355.—5013. *Varities of wheat*. The following six kinds produced per acre, as follows:—

	£	s.	d.		£	s.	d.
Whittington white, 36 bush. value	13	16	9	Brown called clover, 40 bush. value	15	13	6
Surrey white - 36 - -	14	14	0	Essex brown - 40 - -	15	17	0
Snowdrop white - 29 - -	15	9	0	Burwell brown - 45 - -	17	12	0

(*Hillyard in Journ. E. A.*)

8356.—5024. *On the climate requisite to bring wheat to perfection*. Nothing is here said of altitude, latitude, or temperature. The highest altitude on which wheat will succeed on the banks of the Tay, is 450 feet above the level of the sea, where the mean temperature for the year is 46°. Wherever the annual mean temperature is below this, wheat cannot be raised with advantage. (*A. G.*)

8357.—5031. *Throwing out the young plants of wheat*. This is known to take place in many soils in spring after frost, owing to the expansion produced in the subsoil by the freezing of the water which had lodged there. The obvious remedy is furrow draining, subsoil ploughing, and thoroughly stirring the soil by a cultivator. (*Jour. R. A. S. E.*, vol. iii. p. 125.)

8358. *Wheat*. List of fifty-four sorts by M. Vilmorin in *G. M.* 1837, p. 45.

8359. *New kinds of wheat*. Experiments with fifty-five varieties are detailed in *G. M.* 1840, p. 38.

8360.—5041. *Harvesting wheat*. The loss sustained by allowing wheat to become dead ripe before it is cut, has been frequently pointed out, and recently Mr. Hannam has shown that the practice is attended by a loss of at least 26s. per acre, as the following results of a great many experiments will prove.

	£	s.	d.
The value of an acre of wheat cut with the straw quite green, is	-	11	17 0
Green	-	13	6 0
With the grain raw	-	14	18 0
With the grain not quite so raw	-	14	17 4
With the grain ripe	-	13	11 8

Mr. Hannam shows that by wheat being cut raw we have a gain of 15s. per cent., compared with wheat cut ripe, of flour, upon equal measures of land; and again in the weight of straw, of 14 per cent.; advantages which afford a clear gain of 52s. 4d. of flour upon every quarter of wheat. "A gain of 7s. 4s. in the value of every quarter of wheat. A gain of 7s. 6s. in the value of every quarter of wheat, and the straw producing it. A gain of 11. 6s. 4d. upon every acre producing 28 bushels, and of 14. 8s. 2s. upon every acre producing 30 bushels." (*Q. J. A.*, vol. xii. p. 178.)

8361.—5075. *Rye straw* is preferred to that of any other plant for littering horses; and rye is somewhat extensively cultivated about Newmarket for the sake of obtaining the straw for the livery stables. (*J. D.*)

8362.—5081. *Naked barley* (*Hordeum distichum* var. *nudum Metz.*), strongly recommended in common barley flour; absorbs more water, and makes better bread; malts in seven days less time than common barley; three bushels will seed the land as well as four of other barley, with other excellent qualities. See *Kensbury*, in *G. M.* 1840, p. 313.

8363.—5121. *The Hopetoun oat* is an accidental variety brought into notice by Mr. Sheriff in 1824. It is chiefly remarkable for its long reedy straw, which, in a crop of twenty acres in East Lothian, has averaged six feet in length, while the grain is thin in the husk, and nearly as short and plump as the grains of the potato oat. (*Trans. of Highland Soc.*, vol. viii. p. 362.)

8364.—5290. *The value of crops of Swedish turnips, potatoes, and mangold wurzel as food for cattle* is not materially different, provided the crops are alike good of their kind. This is the opinion formed by an East Lothian farmer of great skill and experience, after having made a number of experiments to determine the value of these roots. (*Highland Soc. Trans.*, vol. ix. p. 273.)

8365.—5300. *The Rohan potato*, a French variety, which has been cultivated extensively both in Europe and North America for its large produce, chiefly applied for feeding cattle. Mr. Buel of Albany had nine bushels as the produce of twelve lbs. (*Gard. Mag.* 1840, p. 98.)

8366. *The pine apple potato* keeps quite sound and well flavoured till June.

8367. *The Knepp Castle kidney potato* is large, very mealy, and superior in flavour to any other kidney. The farina is of a pure white, the eyes of the tubers are remarkably full, and hence there is very little waste in paring or peeling them. They have been grown for twenty years in the garden at Knepp Castle, near Horsham, Sussex, without degenerating in the slightest degree. (*G. M.* 1840, p. 102.)

8368. *The best early and late potatoes*. The Manly, a round white potato of moderate and equal size, is one of the best early sorts; and the bread-fruit, a rather large round white potato, a good bearer and a good keeper, is one of the best late sorts. (*G. C.* 1842, p. 97.)

8369. *Comparative merit of different varieties of potato*. Experiments with a view to determine the comparative merit of different varieties led to the conclusion that the *lumpers* and the *cups* are excellent varieties to grow for cattle, because they cover the ground well, do not curl, and produce great weights. In autumn the *white* and *blue Dons* are excellent for family use, and in spring the *old rough black* and *Irish apple*. Through summer the *ash-leaf* is the first that comes into use, and next *Dudgcon's black early*, and the *Flamengo* or *red early*. (*Trans. H. S.*, vol. xi. p. 85.)

8370.—5307. *Soil for the potato*. In the peninsula of Kintyre, the soil is calcareous clay, in which there is found gypsum, an earth said to be congenial to the potato; and there, Mr. Stewart states, that the potato crops far surpass any he had elsewhere seen, either in Scotland or Ireland. (*Brit. Farm. Mag.*, vol. vii. p. 479.)

8371.—5312. *Comparative produce of different modes of preparing the sets, and planting potatoes*. The following interesting experiments were made by the Messrs. Drummond of Stirling, with the Irish blue potato, on the same piece of ground, and under similar circumstances. The space which each experiment occupied was forty square yards, which were drilled and dunged at the rate of thirty tons the imperial acre. They were all planted on 28th May, and raised 12th October, 1832:—

8372. *The first plot* was planted on the plan recommended by Mr. Knight, Pres. Hort. Soc. The tubers were whole, weighing half a pound each, and were planted at the distance of six inches in the row, and the rows four feet apart, and lying north and south; forty square yards required nine pounds of sets, and produced 364 pounds of potatoes; being, per acre, 186 bushels of sets, and 550 bushels of produce; net increase, 414 bushels.

8373. *The second plot* was also planted with similar tubers to the last, at nine inches apart. The seed required weighed sixty pounds, the produce 326 pounds; being, per acre, ninety-one bushels of seed, and 433 bushels of crop; net increase, 402 bushels.

5374. In both these plots the plants were highly vigorous, and early in advance of others planted in the ordinary manner. The potatoes were not too large, but the crop contained a great proportion of small ones.

5375. The third plot was planted the same as the last, but the sets were cut of the common size. The seed required weighed only six pounds, the produce, 276 pounds; being, per acre, nine bushels of seed, and 417 of produce; net increase, 408 bushels. The plants in this plot grew fast in the autumn, and produced by much the largest potatoes; but they did not ripen well.

5376. The fourth plot was planted with sets cut of the common size. The seed required weighed twelve pounds, and the produce 376 pounds; being, per acre, eighteen bushels of seed, and 588 of produce; net increase, 550 bushels. The potatoes in the produce of this last lot were the most equal sized.

5377. The result of these experiments (which were conducted with great care) is entirely contrary to Mr. Knight's theory, and consequent practice. (*Quart. Jour. Agr.*, vol. iv, p. 411.) In the *Transactions of the Horticultural Society*, second series, vol. i. p. 445. to 456. (published in August, 1834), an account is given of a number of experiments made with the greatest care and accuracy, under the direction of Professor Lindley, in the garden of the Horticultural Society, the result of which is conformable to that obtained by Messrs. Drummond. It also appears in the same work that Sir George Mackenzie made experiments of the same kind in Ross-shire, and found the produce decidedly better from sets than from whole potatoes. (See *Gard. Mag.*, vol. x. p. 433. 435. and p. 499.)

5378.—5316. The depth at which the potato should be planted. In warm dry land 9 inches are not too deep; in cold stiff soil, 4 inches would be better; 6 inches is a good depth for average land. Certain experiments conducted in the Hort. Soc. garden, gave the following results: 3 inches deep gave 13 tons; 4 inches, 14 tons; 6 inches, 14½ tons; and 9 inches, 13 tons. At so great a depth as nine inches, sets are apt to perish, unless the soil is dry, light, and warm. The deeper, however, the sets can be safely inserted, the better, for the following reason: potatoes are formed on underground branches; the deeper the set, the more branches will be formed before the shoots emerge from the soil, and consequently the more ample will be the means possessed by the potato-plant of forming tubers. The important practice of earthing up is to effect the same end, by compelling the potato-stem to grow as much as possible under ground. (*G. C.* 1842, p. 155.)

5379.—5330. Distance at which potatoes ought to be planted. Experiments with regard to the cultivation of potatoes gave the best results from sets containing only one eye in each, both in early and late crops. The most eligible distance between the rows varies according to the richness of the soil and vigour of the sort planted in it. Two feet is the least distance that should be allowed for common sorts, and much less for dwarf early kinds; but two and a half feet is in general the most proper distance, as it affords sufficient space for earthing up. The distance between the sets in the rows should be about six inches. The formation of tubers depends on the elaboration of sap by the leaves; and this cannot be duly performed unless the leaves are sufficiently exposed to light. When a number of eyes are retained in each set, or when whole sets are employed, a crowded growth of small stems is the consequence; or, if one take the lead, some large tubers result from it, and a number of small imperfectly matured ones from the small stems with shaded foliage. Equality among the stems tends to produce equal sized tubers, which ought always to be a desideratum; for a crop of very large and small tubers is neither so good in quality, nor so profitable, as one of medium-sized tubers. Single eyes, planted at the above distance, will best insure this. (*G. C.* 1841, p. 185.)

5380.—5327. Earthing up potatoes, according to Mr. Peter Mackenzie, probably originated in wet undrained soils, in order that the roots might be raised above stagnant water. The result of an experiment proved that a very slight degree of earthing up gave fully a third more of increase of tubers, of better quality than those which had been deeply earthed up; while potatoes not earthed up at all gave a produce equal to those slightly earthed up, but rather inferior in quality, from many of the potatoes having their sides green from exposure to the light. (*Q. J. A.*, vol. xii. p. 363.) Earthing up potatoes has no doubt to a certain extent the same bad effect as earthing up turnips, carrots, or parsneps, that of preventing the tuber from swelling so much as it would otherwise do.

5381. The utility of earthing potatoes, provided the soil be deeply worked, and highly pulverised, proved experimentally in the county of Carlisle. Potatoes earthed up in the usual way produced 10 per cent. less than unearthed potatoes. (*Q. J. A.*, vol. v. p. 191.) A good deal depends on the variety of the potato, the stolons of some, such as the *Irish apple* for example, having a tendency downwards, while others, such as the *cup* potato, have a tendency to rise out of the soil.

5382.—5328. The uselessness of earthing up potatoes has been pointed out by Mr. Hayward; and, independently of the effect of earthing up, and other operations between the rows, in destroying weeds and loosening the soil, we should think his practice the best. He says, that a farmer who simply hoed the soil between the rows of potatoes in one of his fields, had a much larger crop than he had in an adjoining field, where the rows were earthed up with the greatest care. A potato placed an inch only under the surface of the soil will produce a greater number of tubers than one planted at the depth of a foot. "I have no doubt," says Mr. Hayward, "if potatoes are planted shallow, and placed wide enough apart to admit of the stems being laid down after the young potatoes are formed; and if the earth between them was then thrown over five or six inches thick, so as to form a flat surface, that it would increase the crop. But this is a very different operation from that which I object to." (*Gard. Mag.*, vol. ix. p. 328.)

5383.—5337. Benefit resulting from the removal of potato blossoms. By a well-conducted experiment on a field of two acres, for which the honorary silver medal of the Highland Society was given, it appears that one third part of the field, being those drills from which the blossoms were plucked in the bud, produced thirty bolls, two bushels. One third part from which the blossoms were plucked when in full flower produced twenty-seven bolls, three bushels; and one third part, being those drills on which the plants were allowed to ripen their seed, produced twenty-six bolls. The difference here, in favour of plucking off the blossoms as soon as they appear, instead of allowing them to remain and ripen their seed, is nearly one sixth part of the produce. (*Highland Soc. Trans.*, vol. x. p. 237.)

5384.—5342. Potatoes should never be covered with straw excepting on the outside of the earth, for straw soon decays, and communicates a bad flavour to the potato. Quantity of sets to an acre 24 bushels, the rows 2 ft. apart, and the sets 6 in. distant in the rows.

5385.—5346. Produce of potatoes. Mr. Knight raised 34 tons and Mr. Parker 52 tons per acre; a ton is 40 bushels. (*G. C.* 1841, p. 247.)

5386.—5354. Potatoes may be preserved by being rasped or ground to a pulp, afterwards pressed into dry cakes by Bramah's or any other powerful press, and then dried like cheeses. Potato cakes of this sort have been found to keep for years perfectly sweet; and, as a great deal of nutriment is thus put into very little bulk, it is thought by some that ships bound for long voyages might find it advantageous to lay in their stock of potatoes in this form. (*Quart. Jour. Agr.*, vol. iv. p. 483.)

5387. Potato flour was shown at Messrs. Drummond's exhibition at Stirling in 1832, which was thirty-eight years old. It was made from damaged potatoes, which, it seems, answer as well as sound ones, and was in the finest condition. (*Quart. Jour. Agr.*, vol. iv. p. 414.)

5388.—5360. Potato hewn forms a rich and excellent manure for wheat, at the rate of four acres of hewn to one of wheat, ploughed in green immediately before sowing the wheat. It is found decidedly superior to stable-yard dung. The mode of preparing it is simply to pull up the stems, and to avoid burying potatoes with it, however small they may be. (*A. Gorrie, in Country Times*, October, 1831.)

5389.—5362. Good beer can be produced from potatoes by grating them to a pulp, mixing it well with boiling water, and then adding ground barley malt. The liquid, being drawn off, is to be hopped in the

usual way, yeast added, and fermentation induced. The flour thus produced, after being bottled, was found greatly to resemble the Paris beer (*Dom Beon in Lardner's Cyclopaedia*).

8390. Beer may be made from parsnips in a similar manner to that from potatoes.  
8391—8394 The distillation of spirit from potatoes is thus practised in France:—The potatoes are boiled by means of a steaming apparatus; and, where the apparatus is good, will be prepared sufficiently in ten minutes. As soon as they are in a proper state, they must be bruised when at as high a degree of temperature as possible, and then thrown, for the purpose of fermentation, into a tub or other vessel containing, for every 1000 pounds of potatoes, 416½ pounds of cold water; the temperature of which, however, should not be below 14° of Reaumur (63° of Fahrenheit). The whole must then be covered up, and allowed to remain. There will be 750 pounds of sediment contained in the quantity of potatoes which has been mentioned; and this proportion, with the 416½ pounds of water, will be quite sufficient to produce a mass, of which the consistency will be that of pap or curdled milk, and the temperature from 48° to 50° Reaumur (140° to 144° Fahr). There are then taken 31½ pounds of the malt of barley, which is steeped in 250 pounds of water that has been previously heated to the height of 60° Reaumur (167° of Fahr), and the whole is allowed to remain until it shall have cooled to the temperature of 22° of Reaumur (81½ of Fahr). There are then added 22½ pounds of yeast, which is mixed by being actively stirred, and the whole is then well covered and allowed to remain. When the mass of fermenting potatoes is cooled to the temperature of 38° of Reaumur (117½ of Fahr), the fermentation is stopped by adding 416½ pounds of cold water, and the whole is well stirred together. This mass having fallen to the temperature of 25° Reaumur (85½ Fahr), the prepared malt which has already begun to ferment, is added, the whole is again well stirred together, the vessel very lightly covered, and the fermentation allowed to proceed. This latter operation takes place very regularly and terminates in from forty-eight to sixty hours. The fermented mass assumes a spirituous odour, and furnishes, on distillation, so abundant a quantity of spirit, that, for every 100 pounds of potatoes, there are obtained eight French pints of spirit, in which, according to the scale of Richter there are thirty per cent of alcohol. If, before carrying the fermented mass to the still, it is passed through a sieve of iron wire of close meshes, the pulp of potatoes is kept back, and the spirit is then more pure, and more pleasant to the taste and smell. This will be still more the case, if there be added to this mass half a pound of potash for every 100 pounds of potatoes, before submitting it to distillation. If it is wished to have a spirit analogous to that obtained from wine, it must be rectified accordingly (*Molem's Recueil Industriel, and Quart Jour Agr*, vol. iii p 321).

8392—8395 Mincing potatoes, and mixing them intimately with straw cut into chaff "completely prevents the fermentation of the potatoes in the paunch from injuring the cattle. They eat up the prepared mass with relish, are soon satiated, and then lie down with ease and comfort, and of course fatten rapidly." (*Q J A*, vol. vii p 244)

8396—8399 Frozen potatoes. When frozen potatoes are thawed, they frequently do not give a fourth part of the starch which they give before being frozen. The cause of this, it appears, is, that the starch, being contained in the cells, or vesicles which constitute the principal part of the parenchyma of the potato, is, in the case of potatoes not frozen, set free by the operation of the rasp or grater in grating them down for starch. When the potato has been frozen, however, and is afterwards thawed the cells are no longer firmly fixed in the fibrous matter of the potato, and the grater has no longer any power to tear them to pieces. Every one knows that the most mealy part of a potato is immediately within the skin, and M. Payen has discovered that by far the greater number of cells of starch are in that part of the tuber, and that there are comparatively few towards its centre. M. Payen also found that the freezing of the outer part of the potato, and the subsequent thawing cause that bitterness which is invariably found in frosted potatoes. Before the potato is frozen, the bitter principle, being contained in the skin, is readily removed by paring or peeling, but, when the structure of the parenchyma of the potato is deranged by freezing and thawing, the bitter matter is communicated to the adjoining parts of the potato, in consequence of their comparatively fluid state. The inhabitants of Peru dry their frozen potatoes, and thus preserve them for food for an indefinite length of time (*G M* 1839, p 186). If gradually thawed in cold water, and cooked immediately afterwards, they are eatable, but in a few days become bitter, from the diffusion of the bitter of the skin (*G C* 1841, p 116).

8394—8397 Dale's hybrid turnip was originated, about 1828, by Mr Robert Dale, of Libberton West, near Edinburgh. It is tankard-shaped, and resembles the Swedish or yellow turnip in colour. It is equal in size to the white globe, superior in size to most other varieties whether of white, yellow, or Swedish turnips, and is found to produce a greater weight in a given space, and at a given expense of manure,

than any other turnip hitherto introduced. It is not so hardy as the Swedish, and it runs to flower rather sooner in the spring, but, with these exceptions, it is the best of all field turnips. (*Quart Jour Agr*, vol. iii. p 578.)

8395—8410 The most economical mode of dividing a field of turnips which is to be eaten off with sheep I have this year two pieces of turnips, of ten acres each, nearly square, which I intend to divide by hurdles into eight divisions each, for eating on the ground by sheep and young cattle. now it is plain that if I divide them straight across the field, from hedge to hedge, I shall have seven settings of hurdles, of 280 yards in length, in each field, making in the whole a length of 3080 yards for setting hurdles at different times.

To save labour, I therefore adopt the method explained in the annexed diagram, *fig. 1180*.

Suppose the figure, A B C D, a square field of ten acres, then a b will be the first setting of hurdles, c d the second, d e the third, e f the fourth, f g the fifth, g h the sixth, h i the seventh, and i m the eighth; in the whole,

eight settings of 110 yards each, or 880 yards, in both pieces 1760 yards, or one mile, and the turnips will be eaten in rotation, as the plots of ground are numbered

Length of harding in former way	-	-	-	-	8080 yards
Length of ditto in latter way	-	-	-	-	1790
Saving of labour	-	-	-	-	1220

(*Young's Annals of Agriculture*, vol. xlii. p. 346.)

8396.—8413. *The taste of turneps in milk, butter, and beef*, it is said, may be prevented by the following means:—"Never allow the cow to taste of the roots within six or eight hours of milking, but feed her immediately after each milking, and do not give her any more of the roots at a time than she will eat in two or three hours, and be careful that she does not get any more till after she is milked again. By this method cows may be fed on rutabaga or other turnips and no person will be able to discover the taste in the butter or milk. Upon the same principle, those who wish to feed their cattle on turnips may do so without any danger of affecting the taste of the beef provided they will omit feeding with this kind of food two or three days previous to the killing. Cases have occurred where the beef was rendered unfit to eat, on account of the animals eating a few turnip-tops or cabbage leaves before being slaughtered. The difficulty may be obviated as mentioned above." (*Brit. F. M. N.*, vol. iv. p. 361.)

8397.—8420. *Storing turnips*. By experiment it was found that raising them in stacks above the surface by means of wattled stakes to prevent them from spreading out, and when the stack is as high as it will stand, thatching them is superior in every point of view to burying them in the soil in the manner of potatoes. (*Jour. A. E.*, vol. ii. p. 228.)

8398.—8433. *Fly on turnips*. The following mode of prevention has been resorted to with success at Green Hammerton, Yorkshire. A board, about eighteen inches in breadth and sufficiently long to cover four ridges of turnips, was made to run upon wheels high enough to allow the board to pass over the turnips without touching the tops of them. The lower side of this board was painted with white paint, which the men provided themselves with, and took into the field, and during the night (at which time the fly is more injurious and destructive than during the day) the instrument was wheeled from one end of the field to the other. The insects, on being disturbed, of course immediately fly or jump up and stick to the paint, and at the end of every set of ridges the board was almost covered with them. (*Ireos Mercury*, and *Report Don. Agr. Association*.)

8399.—8444. *The white or Belgian carrot* produced on Lord Ducie's farm at Whitfield, at the rate of 26 tons 3 cwt. per acre. The soil is a deep sandy loam belonging to the new red sandstone formation. The seed was sown in the second week in April on land which had been ploughed 10 inches deep. It was sown on the flat, in rows 18 inches apart, by the common suffolk drill. The seed had been mingled with damp sand for several days previous as well to sprout it partially as to render it capable of being drilled, as carrot-seed clings so much together. They are thinned out when a fortnight old to intervals of 6 inches in the row, and two horse-hoings, with a hand-hoeing whenever the weeds made their appearance, was all the cultivation they received. The result is a crop not only much more valuable per ton than any other green crop we have but also heavier per acre and raised at an expense less by at least one-half than that attending the cultivation of the turnip. (*Journ. A. E.*, vol. ii. p. 40.)

8400. *The white carrot*. The produce with Sir C. M. Burrell in Sussex was upwards of 1,300 bushels per acre after separating the green tops. Some of the roots had penetrated as deep as 3 feet 5½ inches, so that the white carrot cannot be a very scouring crop. The soil was loamy and well and deeply drained and subsoil ploughed but not manured. (*B. F. M.*, n. s. vol. iv. p. 466.)

8401.—8413. *Carrot seed*. Messrs. Drummond, the eminent seedmen of Stirling state that the carrot crop in the field may almost always be insured other circumstances being favourable, by bringing the seed to the point of vegetating before sowing. This is done by mixing it with sand or earth kept moist and turned occasionally for several days. They also recommend some nourishing compost to be placed under the seed in the drills or sown along with it. They have made an experiment to prove that carrots may be grown to great advantage in peaty soil, and that they may be even grown in old worn out garden soil by mixing peat and dung together and putting the compost thus formed in a gutter made by a wedge-shaped dibble six inches wide at top, six or eight inches long and at least a foot deep, the seed being sown immediately above the compost. (*Quart. Jour. of Agr.*, vol. iv. p. 410.)

8402.—8471. *The parsnep* is superior to all other roots for fattening hogs, but they must be given raw, for the boiling of the root renders the bacon flabby. Parsneps will fatten a hog in six weeks, more especially if some milk is given with them. The roots are never to be washed, because it is found that washed roots are found to surfeit both hogs and cattle. (*G. C.* 1842 p. 337.)

8403.—8473. *Parsneps in Guernsey* produce from 9 to 11 tons per statute acre, which are excellent for fattening oxen or pigs, and when boiled will fatten poultry in an extraordinary manner. The produce of Aittringham carrot in Guernsey, as compared to that of the parsnep was as 261 to 840. According to Sir Humphry Davy, 1000 parts of parsnep afford 90 parts of saccharine matter and 9 of mucilage, and 1000 parts of carrot, 90 parts of sugar and 3 of mucilage. The greater proportion of mucilage in the parsnep may be the cause of its superior fattening properties. (*Jour. A. E.*, vol. i. p. 422.)

8404.—8488. *Mangold wurzel* proved to have greater fattening properties than Swedish turnip by Earl Spencer. (*Journ. A. E.*, vol. ii. p. 236.)

8405.—8516. *Hympyrum aspernum*. Mr. Gorrie observes, it is assuredly liked by horses and cattle, and will soon recommend itself to the cottager and dairyman as a powerful auxiliary to clover, in summer and autumn. (*Highland Soc. Trans.*, vol. ix. p. 249.)

8406.—8517. *Emothra bifennis*, a biennial plant growing to the height of four or five feet is said to make a very good forage plant in some parts of Germany. It is of the easiest culture, more especially in deep sandy soils. The roots are fusiform, white, sweetish, and in Germany are frequently used in cookery, like those of the skirret or scorzonera.

8407. *Lupinus polyphylus* has been tried as a forage plant by the Earl of Mansfield and found valuable in good sandy loams, but it is thought inferior in nutritive properties to the lucern.

8408.—8522. *Trifolium elegans* D. Don., a hybrid *Bon. Jardenii* the elegant hybrid or Alsike clover, apparently a gigantic variety of the common white clover has been cultivated in Sweden for upwards of forty years, though only lately brought into notice by M. Vilmorin. It produces trailing shoots five or six feet in length, is remarkably hardy, and prefers strong moist soil. We believe it to be the same plant which we collected in Poland in 1813, and of which we exhibited specimens at the Linnean Society about the end of the following year. In England it is now being cultivated by Mr. W. Taylor F. L. S. who conceives a very high opinion of its value to the agriculturist. It does not suffer, he says, from the severest frost, its growth being merely suspended, while its foliage is not injured, it may be readily propagated on a large scale by division of the root, and it flourishes in inferior soil.

8409.—8527. *Trifolium incarnatum* is considered in Italy as the earliest of clovers, as particularly calculated for dry soils and as preferring the mountain to the plain. It is an annual and succeeds best when sown in the autumn, after the corn crop has been removed. (*Quart. Jour. of Agr.*, vol. iii. p. 729.) *Trifolium incarnatum* is found of great value in filling up blanks in fields of common clover being sown immediately after carrying the corn crop.

8410. *Trifolium giganteum*, the Affghan clover, thrives in England during summer, but is too tender for winter. (*Gard. Chron.* 1841 p. 838.)

8411.—8560. *Clover* is dried in the hilly parts of Germany by resting it, immediately after being mown, against portable treasels, as corn is dried in Sweden and Norway. (*L'Agronomie*, vol. i. p. 136.)

8412.—8518. *The Prangos hay plant*, is described in *Moorcroft's Travels*, vol. i. p. 288., as singularly

productive of forage; but though many attempts have been made to bring the seeds to Europe in a live state, the attempt has not yet been attended with success. (G. C. 1842, p. 351.)

8413.—5623. *Gorse*, instead of being bruised as formerly before being given to horses or cattle, is now cut by machines like those in use for cutting hay and straw. It is found that both horses and cattle feed with much greater avidity upon the gorse when cleanly and regularly cut, than when reduced into a consistency nearly approaching a pulp, by bruising or crushing. In this state also it is apt to become sour in the summer season, in which state it is rejected by all animals. (Brit. F. M., N. S., vol. iv. p. 359.)

8414.—5643. *Old pasture compared with new.* John Boswell, Esq., of Kingcastle, Aberdeenshire, has long been of opinion that permanent pasture, instead of being a good thing, is a bad thing. After recapitulating his experience during several years, and strongly recommending thorough under-draining, deep ploughing, and manuring, he concludes thus:—"I maintain that, except a few favoured spots, such as banks of rivers, &c., no ground can, without loss, be left long in pasture; and that it appears to me, four or five years is, generally speaking, the longest period land should be allowed to lie in grass. If pasture be the object, at the end of that time the ground should be broken up as arable land, and then returned to grass again. I maintain, that without grass severely cropped land cannot be restored to full fertility; and without cropping, grass cannot be made to continue at the maximum point of verdure and utility. Lastly, I maintain, no land, under any circumstances, ought to be cut in hay, if intended to remain some years in pasture; and, if cut as hay, every kind of land ought to be directly ploughed, and again put through the rotation." (Quart. Jour. Agr., vol. iv. p. 790.)

8415.—5647. *The great object of mixing different grass and herbage seeds together*, is to stock the surface of the soil at once so thickly with useful plants as to prevent weeds from rising up through them. Experience has proved that this cannot be done so effectually when only one or two species of grass or herbage seeds are employed, as when a greater number are made use of; and the reason appears to be found in the diversity of soils and situations. In general, the richer the soil the smaller will be the number of species which it will require. When the selection of grass seeds is judicious, there will be a constant succession of herbage kept up by them the whole year round, as grasses of several sorts grow at all times when the temperature is above the freezing point.

8416.—5647. *Grass seeds.* By an experiment made by Messrs. Drummond of Stirling, with a view to ascertain the proper covering for grass seeds, it appears that the common rye grass will penetrate through a deeper covering than any other agricultural grass, having risen through a layer of soil of three inches in thickness. The *Poa* and *Agrostes*, which have very small seeds, will not bear more than a quarter of an inch of cover; and from a quarter to half an inch appears the proper depth for the other sorts. Hence, instead of using the common harrow for covering grass seeds, the surface should merely be rifled by a brush, or some implement in imitation of one, and well rolled. (Gard. Mag. 1841. p. 509.)

8417.—5653. *The Tussock Grass* (*Festuca flabellata* Lamarck, *F. caespitosa* Koen. et Schultes, *Dicella caespitosa* Forster), a native of the Falkland Islands, where it is perennial and grows six feet high, with fan-shaped leaves, like those of an Iris, is expected soon to be introduced at Kew, whence some of Ward's cases have been sent out for bringing it home. Every animal is said to feed upon it with avidity, and get fat in a short time. It may be planted and cut like the Guinea grass of the West Indies, but unfortunately it will only thrive where its roots have access to salt water. There is another kind of Tussock grass in the Falkland Islands, the *Carex tridactyla*, which grows only 1½ feet high, and, like other *Carexes* is of no use as a forage grass. (G. C., 1843, p. 181. and 190.; and the Jour. A. E., vol. iv. p. 17.; and Hooker's Notes on the Botany of the Antarctic Voyage, &c., 1843, p. 52.)

8418.—5655. *Italian rye grass* is found far ahead of all other grasses in early spring, and therefore it is particularly adapted for coming in after the turnip season as early green food for cattle. It should be sown in autumn along with *Trifolium incarnatum*, which keeps pace with it in early and vigorous vegetation, even in Scotland. (Brit. Farm. Mag., vol. 1, 2d Series, p. 502.)

8419.—5656. *The Italian rye grass*, Mr. Lawson found to be the same variety as Stickney's rye grass. It is considered superior to any other grass in producing winter herbage, and to be more hardy than the common rye grass. (Highland Soc. Trans., vol. x. p. 28.)

8420.—5693. *Poa nemoralis* var. *nerosa*, the Hudson's Bay meadow grass, has been brought into notice by Mr. Bishop. Its value arises from a property which it possesses, and which is common to no other grass cultivated in Scotland, viz., that of the flower stem, after being cropped, reproducing shoots from the stem as well as the root: in consequence of which it continues growing throughout the whole year, particularly in the latter part of summer and autumn. A specimen mown off cold damp land on the 14th of April, 1836, averaged from 18 inches to 20 inches in length (G. M. 1837, p. 283.)

8421. *Bromus pratensis* L., *B. erectus* Sinclair, is strongly recommended by M. Vilmorin for poor soils liable to be burnt up with drought. Sheep, he says, are remarkably fond of it. (G. M. 1841, p. 467.) It is the only grass

8422.—5717. *Number of kinds of grasses required in laying down permanent pasture.* A judicious writer in the Quart. Jour. of Agr. is of opinion, that more of these grasses are brought into notice than their good properties will warrant. Independently of perennial rye grass and white clover, which must always occupy a large share of every permanent pasture, perhaps five or six of the others are all that are worth cultivation. It is true, many worthless grasses will grow up among our most carefully laid down pastures, and they no doubt assist in thickening the sward. But this is surely no adequate reason to sow them, and if it be necessary to sow a certain quantity of seed to cover the ground, that quantity should be composed of the best kinds. One reason for sowing a number of kinds is, that more plants will thrive closely together of different sorts than of the same sort. Allowing this to be the fact, there is still no necessity for incurring the trouble and expense of sowing worthless kinds, when a variety of them will grow naturally out of the soil to form a thick sward. Should the different kinds arrive successively at their greatest vigour, seeds of the best sorts can be selected on account of their coming to maturity at the different seasons when pasturage is required. It seems that 4 bushels will just furnish as many fertile seeds, that is, seven to the square inch, as there are plants in that space in a natural pasture; but if even more are required to render the pasture better, more of the best kinds only should be sown to insure the requisite thickness of sward. (Quart. Jour. Agr., vol. iv. p. 414.)

8423. *Kinds and qualities of grass seeds for laying down land.* The most valuable article which has appeared on this subject since the publication of Sinclair's *Horius Gramineus Woburnensis*, will be found in the Quarterly Journal of Agriculture, vol. iv. p. 714—724. This article is by Mr. Lawson, an eminent seedsman in Edinburgh; who for a number of years has directed his attention to the subject, with a degree of success which has been acknowledged by the first agriculturists in Scotland to be pre-eminently great. After giving a short description of thirty species or varieties of proper grasses, and eleven herbage plants, of which he has seeds for sale, he enumerates six other herbage plants, all Leguminosæ, the seeds of which are not yet articles of commerce, but which he says may be advantageously introduced into cultivation, as soon as their seeds can be obtained. These are, *Lotus major*, *Ficia Cracca*, *V. sepium*, and *V. sylvatica*, *Lathyrus pratensis*, and *Trifolium medium*.

8424. *Sowing the seeds of grasses and herbage plants by weight*, instead of the general practice of sowing the grasses by measure, and the clovers by weight, is strongly recommended by Mr. Lawson. "For, although in grass seeds the greater weight of one variety is no criterion of its superiority over another variety of less weight, yet a greater weight in the same variety always denotes a superior quality. Thus, when seed is light, and consequently inferior, the greatest number of seeds is obtained by adhering to a given weight; and hence there is the chance of nearly an equal number of plants springing up as when the seeds are plump and heavy. But a given weight of measure of seeds does not indicate the relative number of plants that will spring up; because there is both a difference in the relative bulk and specific

gravity of seeds, and there is also a difference in the number of seeds that grow from a given quantity." (p. 719.)

8425. The weight of the seeds of grasses, per imperial bushel, is next given by Mr. Lawson; and the differences between the seeds of different species in this respect is most remarkable. Of thirty species, the heaviest appears to be the common perennial rye grass, a bushel of which weighs from eighteen to thirty pounds; and the next heaviest appears to be the crested dog's-tail grass, which weighs twenty-six pounds. The lightest seed is that of *Avena* [*Trietum*] *flavescens*, a bushel of which weighs only five pounds, and the next lightest is the meadow fow-tail grass, which weighs five pounds and a quarter. *Anthoxanthum odoratum* and *Alopecurus geniculatus* weigh each six pounds. *Aira flexuosa*, six pounds and a quarter; *Poa glauca*, seven pounds and a half; *Elymus arenarius* and *Festuca duriscula*, each nine pounds and a half, and the remaining species weigh from ten to sixteen pounds. Rye weighs sixty-two pounds the bushel.

8426. The weights of clover and other herbage plants are much less various. Burnet weighs twenty-four pounds and a half; sainfoin weighs twenty-six pounds; *Achillea Millefolium*, twenty-eight pounds and a quarter; ribwort, fifty-one pounds and a half; *Medicago lupulina* (the nonsuch of English farmers, and the yellow clover of the Scotch) weighs sixty-three pounds and three quarters; and the different species of clover (*Trifolium*) from sixty-two to sixty-five pounds.

8427. With reference to the culture of grasses in Britain, Mr. Lawson observes that, wherever land produces the cereal grains and other cultivated plants, the pasture and herbage grasses will grow with vigour. Plants of this kind, he observes, are improved by different kinds of soils, and more especially with relation to their states of dryness or moisture. As a convenient arrangement for practical purposes, he classes all soils under light, medium, and heavy, and he has composed twelve different tables, each containing the quantity of grass seeds, per Scotch acre, for these three divisions of soil. Whoever, whether in Britain or America, wishes to sow grasses on a large scale, will find it worth their while to correspond with Mr. Lawson, with reference to the subject of these tables, because every year he is adding to his experience, and in all probability improving the selection. We shall, therefore, not copy them into our pages in detail, but merely give their titles with a few remarks, chiefly with a view of showing how much greater the number of species is which Mr. Lawson recommends than what is commonly sown, and yet how much smaller is the quantity of seed per acre.

8428. *Grass and herbage seeds for alternate husbandry.* For one year's hay, twenty-two pounds of annual rye grass, ten pounds of red and two pounds of white clover. For one year's hay and one year's pasture, eight pounds of annual and eighteen pounds of perennial rye grass, three pounds of *Phleum pratense*, five pounds of red and five pounds of white clover, and two pounds of nonsuch. For one year's hay and two years' pasture, twenty-eight pounds of perennial rye grass, two pounds of *Phleum pratense*, two pounds of red, six pounds of white, two pounds of cow clover, and two pounds of nonsuch. These proportions are for soils suited for the turnip husbandry, in heavy soils, from two to four pounds of *Phleum pratense* may be added for one year's grass.

8429. *Grasses and herbage plants for permanent pasture.* Of proper grasses, seven species are employed, of proper clovers, three species and also the nonsuch. The proportions are given for laying down without a crop and also with a crop, and it is worthy of remark, that in the latter case the quantity required is not much above half what it is in the former. Without a crop, seventy-five pounds are required for a light soil, and eighty-two for a heavy soil, while with a crop, forty-one pounds and a half in the one case, and forty-five lbs. in the other, only are required.

8430. *Grasses, &c., for permanent pasture in ornamental parks.* Of proper grasses, fourteen species are employed, besides the clovers mentioned in the preceding paragraph. It is added, that *Achillea Millefolium* may be added in dry soils, sainfoin in dry calcareous soils, wild endive in heavy soils, and from one to two pounds of parsley per acre on lands where sheep are apt to get the rot.

8431. *Grasses and herbage plants for lawns, bowling-green, &c., kept constantly under the scythe.* Of proper grasses, fifteen species are employed, together with the common white clover. On each soil, Pacey's perennial rye grass, more than one fourth part of the proper grasses, and the quantity of white clover per acre, varies from six to twelve pounds.

8432. *Grasses and herbage plants for grounds much shaded with trees.* Twelve species of proper grasses and white clover.

8433. *Grasses, &c., for healthy and moory lands which have been pared and burned, or scarified for the purpose of producing herbage.* The following cheap mixture is recommended. — Mixed hay seeds twenty-five pounds, and white clover, six pounds, with a crop, and forty pounds of mixed hay seeds, forty-five pounds of rye, and nine pounds of white clover, without a crop. When land of this description is situated 500 feet and upwards above the level of the sea, sheep's fescue and the two allied species, and *Poa glauca*, may be added, at the rate of two pounds each.

8434. *Grasses for improved deep peaty ground intended to lie in grass.* Perennial rye grass, ten pounds, *Phleum pratense*, eight pounds, *Agrostis stolonifera*, two pounds, *Alopecurus pratensis*, two pounds, and *Trifolium repens*, eight pounds, are recommended, when they are to be sown with a crop, when without a crop the proportions are, eighteen, twelve, three, three, and twelve pounds.

8435. *Grasses for land in preparation for irrigation.* We shall take the liberty, in this case, of copying the table verbatim —

	Light Soil		Medium Soil		Heavy Soil.	
	With a Crop.	Without a Crop.	With a Crop.	Without a Crop.	With a Crop.	Without a Crop.
Perennial rye grass	10	18	7	12	7	12
<i>Agrostis stolonifera</i>	2	4	2	4	2	6
<i>Alopecurus pratensis</i>	2	4	2	6	4	8
<i>Festuca pratensis</i>	2	4	2	4	2	4
<i>Festuca lolacea</i>	4	7	4	7	4	7
<i>Poa trivialis</i>	2	4	2	4	2	6
<i>Poa sativata</i>	1	2	2	4	2	4
<i>Phleum pratense</i>	4	6	6	9	7	10
	27	49	28	50	32	57

8436. *Grasses for lands which are occasionally subject to the overflowing of lakes and rivers, or which are always in a very wet state.* These are, *Poa aquatica*, six pounds, *Poa sativata*, six pounds, *Festuca lolacea*, four pounds, *Phleum pratense*, six pounds; *Alopecurus geniculatus*, six pounds; *Agrostis stolonifera*, four pounds.

8437. *Grasses for rabbit warrens, or light sandy soils.* These are perennial rye grass, fourteen pounds, *Anthoxanthum odoratum*, one pound; *Festuca duriscula*, one pound, *Festuca ovina*, one pound, *Festuca rubra*, one pound; *Cynodorus cristatus*, two pounds, *Poterium Sanguisorba*, four pounds; *Achillea Millefolium*, half a pound; *Trifolium repens*, six pounds, *Trifolium minus vel procumbens*,

two pounds; *Medicago lupulina*, two pounds. If this mixture be sown without a crop, a bushel and a half of rye grass may be sown along with it.

8438. *For drifting sands, which are to be consolidated, and have a sward produced upon them by sowing.* These are, *Elymus arenarius*, ten pounds, which should be mixed with clay and straw ropes cut into rib-warps, or light sandy soils, may be sown.

8439. *For dry grassy situations, which resist a sward from all ordinary means.* These soils may be sown with *Agrostis vulgaris*, two pounds; *Poa annua*, four pounds *Briza media*, four pounds, *Aira flexuosa*, one pound, *Trifolium minus vel procumbens*. We repeat our strong recommendation of Mr Lawson, as an agricultural seedsman, to all persons residing near Edinburgh who have lands to lay down in grass. We are not less anxious to recommend Messrs Drummond of Stirling, Messrs. Dickson and Turnbull of Perth; Messrs Cormack and Son, and Mr Gibbs, of London, and M. Vilmorin, of Paris, to all those similarly circumstanced in their respective localities.

8440. *Mixtures of grasses for the alternate husbandry.* From the result of an experiment made by Mr. Shireff of Mungoswells (*Quart. Jour. Agr.*, vol II p 242), it appears decidedly preferable to use a mixture of seeds, even where a single crop of hay, to be succeeded by a year's pasturage, is to be taken. The grasses sown were cock's-foot, hard fescue, cat's-tail, rye grass, and red, white, and yellow clover. The rye grass was conspicuous for growing early in spring as well as late in autumn, and remaining comparatively unproductive in the summer months. The cock's foot, throughout the season, put forth new leaves with rapidity, after being cut with the scythe, and produced culms to the hay crop only, the fescue planted thinly, and also grew rapidly after being cut, the cat's-tail was later in producing flower-stalks, than the other grasses used in the experiment, and, after being cut, did not put forth new leaves so rapidly as the cock's-foot and fescue, but, in every instance, it produced numerous culms, yielded blossomed, at the same time as the red clover, and where a part of the field was four times mown, white a rich crop of culms to the last. The produce, as compared with that of clover and rye grass only, sown in the same field in the same season, was about a ninth part greater, and the extra expenses of the seed about a fifteenth part. Had the clover failed to grow along with the rye grass, as it frequently does, the difference in the produce would have been much greater. The great advantage of a numerous combination of grasses is that the failure of a crop is rendered next to impossible. It is also found that a mixture of grasses is less injurious to the succeeding corn crop than rye grass only. The family of grasses Mr Shireff observes, forms a useful class of machinery in the manufacture of productions for the dairy, the shambles, and the manufacturer of clothing, but in order to take advantage of the raw materials, air and moisture, so bountifully supplied by nature, the most efficient machinery, must be employed. The husbandman who clothes his fields only with rye grass and clover employs a limited machinery, the former being unproductive in summer, the latter moderately so in spring, but when he, for this purpose, uses a variety of plants, differing in their habits of growth and periods of luxuriance, a numerous and powerful machinery is kept successively in full operation.

8441. *Poa nemoralis* was found by Mr Taunton to produce a thick sward in plantations where every other grass was killed. He says, "its rich nutritive quality, its beautiful and perpetual verdure and, above all its quality of flourishing under a dense cover of trees appear to me to render it peculiarly valuable for the particular purpose of rendering ornamental, and also of turning to a profit the size of grown up plantations and thick groves, which are, usually, in a state of complete nakedness" (*Quart. Jour. Agr.*, vol III p 418).

8442.—5768. *Irrigating meadows with liquid manure* from the common sewers of Edinburgh. This has been practised to a considerable extent in the neighbourhood of Edinburgh and according to Mr Stephens (*Practical Irrigator and Drainer*, p 76), it is one of the greatest improvements ever made in agriculture. The inhabitants of Edinburgh, however, are of a different opinion, and according to a pamphlet on this subject published in 1839 entitled *Papers relating to the Noxious Effects of the Fetid Irrigation around the City of Edinburgh* it appears that no horse or other animal will eat a particle of the produce of these meadows, either while growing, or when first cut, and the cows when first put to eat it have for some days an absolute loathing, and can hardly be got to feed upon it, but when they do, it causes an immense flow of milk, which is kept up by this grass, and what is called dreg (brewers' wash), but whenever the supply of this grass becomes short, they are found to be incapable of digesting the usual fodder of cattle, and completely diseased, and get unfit for any purpose almost (*G. M.* 1840, p 370).

8443.—5820. *To destroy moss in old turf*. "It is a singular fact, but not generally known to agriculturists, that by merely lifting the turf of an old pasture field that is overrun with moss and ploughing and loosening the subsoil, and then laying the same turf down again the whole of the moss will disappear the first season without applying either water or manure to the surface" (*Stephens on Irrigation and Draining*, p 9).

8444. *Renovating defective meadows.* The late Mr Sinclair, of the New Cross Nursery had perhaps more experience as he certainly had more science and skill, in this department, than any other man. In his excellent work the *Horius Gramineus Woburnensis*, he recommends first ascertaining that the meadow is completely under drained, then stirring the surface by harrowing it, in all directions, the best barrow for which is unquestionably that of Finlayson. After this he gives a thorough top-dressing of rich finely divided compost, he again harrows and cross harrows, and then sows from two to six pecks per acre of grass and clover seeds. For a meadow of low rich alluvial soil he employs meadow fox-tail, meadow cat's-tail, meadow fescue, rough-stalk meadow grass, crested dog's-tail grass, sweet-scented vernal grass and perennial red clover. In two years such a meadow will be thoroughly renovated, and will bear abundant crops of hay.

8445.—5592. *New fibre plants.* Mr Taylor of Holbrooke, near Ipswich, sowed five rods of ground with the seeds of *Sida Abutilum*, a malvaceous annual, and received from it at the rate of 15 cwt of saleable fibre per acre which he had manufactured into excellent ropes. *Malva crispa* *M. peruviana*, and *M. mauritiana* also produce fibre which might be applied to the same purpose as that of *Sida Abutilum*; more especially *Malva crispa*, a very common annual in British gardens. (*G. M.* 1840, p 38).

8446.—6101. *Camelina sativa*, an annual a native of Siberia, has been long cultivated on the Continent as an oil plant, and has lately been tried in this country by Mr W Taylor, F. L. S., of Holbrooke, near Ipswich, with great success. In 1839, Mr Taylor obtained upwards of 50 bushels of seed from an acre, which produced at the rate of 12 lbs of oil per bushel, worth 2s 6d per gallon, and 44 lbs of oil cake.

8447. *Madia sativa*, an annual, a native of Chili, cultivated in gardens as a border flower, has also been grown on a considerable scale in 1839 by Mr Taylor who obtained 33 bushels of seed from an acre, which being crushed produced 250 lbs of oil, and 410 lbs of oil-cake. The oil alone was worth 9s. (*Gard. Mag.* 1840, p 38).

8448.—6111. *Buckwheat* is ground generally into grits by means of handmills, or lever hammers, and is made either coarse or fine. The coarse sort is used for gruel, and the fine sort for cakes and biscuits. In some places they even make use of the first grinding with the bran more or less, in addition to the finer flour, for baking household bread. It also serves to fatten hogs or poultry in a short time. The principal method to cleanse and separate the husk is, to pour boiling water on a given quantity of cleaned buckwheat, to stir the mass about with a stick, and draw the water off, then to pour cold water upon it, having first stirred it about well. In a quarter of an hour after, the buckwheat is taken out with the hands, and the water squeezed out. In the summer it is dried in the sunshine, and in winter in a warm room, and spread on the floor. As soon as it is quite dry, it is ground in a hand-mill or a stamping-

machine into grits, in which state it is very clean and tasteful. The flour obtained from the same is dainty and very fit for cakes." &c. (*Com. Board Agr.*, vol. 1.)

8449.—6199. *The extirpation of ferns in pastures*, where the plough cannot be used. The Highland Society having offered a premium for the best essay on this subject, two were produced and published. (*Trans. H. S.*, vol. xx p. 371.) In both, the writers, finding that ferns grew always in dry land, propose to irrigate it for a few years. A knowledge of the functions of the leaves of plants would have suggested the cutting off of these in their incipient state, as soon as they made their appearance above the soil, and consequently before they had time to return any nutriment to the root; which will not only kill ferns, but every other plant whatever.

8450.—6218. *The varieties of the horse described by Professor Low*, are: 1. The race horse; 2. The hunter; 3. The Connemara, or Irish pony breed, of Spanish origin; 4. Classes of British horses: viz. Zetland ponies; Orkney ponies; Highland ponies; Welch Dartmoor, Exmoor, and Hampshire horses; hack horses, and Galloways of the borders; 5. The old English black horse; 6. The Cleveland bay; 7. The Suffolk punch; 8. The Clydesdale breed. (*Low's Domestic Animals*, vol. 1.)

8451.—6594. *A machine for fixing horses while being shod*, of a simple and effective description, has recently been invented by Mr. James Catcleugh, millwright in Haddington, a mechanic of very great genius, which will be found described and figured in the *Quart Jour Agr.*, vol. iii p. 510.

8452.—6598. *Roadway's concave horse shoe* is particularly applicable in the case of horses that have to pass over wood pavement, and it is also said to contribute much to the comfort of the horse in every other description of road. (*Brit F M, N S*, vol. vi p. 426.)

8453.—6684. *The following plan of feeding horses* has been practised by Dr. Sully of Wivelscotcombe, in Somersetshire, for upwards of twenty years. In Dr. Sully's stables there are no racks for holding hay; for in his opinion a horse with a well filled rack will consume and spoil upwards of thirty pounds of hay in twenty-four hours, whereas, if the hay were cut down, and mixed with a due proportion of cut straw, and bruised or coarsely ground oats or other grain, ten pounds are sufficient. In the loft, above the horses, Dr. Sully has prepared proportionable quantities of the food with which his horses are daily supplied; and a very simple method has been devised to convey it, when mixed, to the manger of each horse. A wooden pipe is made to pass from the loft into each of the mangers, and close by the mouth of the pipe, in the loft is placed a tub, of size enough to contain what is sufficient food for a horse for twenty-four hours. To prevent the horse, in searching for grain, from tossing out of the manger the mixed food which is dropped into it, oak crossbars, twelve inches distant, are nailed over it, between these bars ample space remains for the horse to feed. As there can be no dependence on the measured quantities of grain or other food given to the horse, from the variation at times in the respective weights of equal quantities, Dr. Sully recommends, and, indeed, regards it as necessary, that grain of all kinds, and also the cut hay and straw, should be carefully weighed. When all the ingredients are so prepared, the proportions for each horse are allotted. From the following table will be seen the different articles of food, and the quantities and weight of each, which the horses should receive:—

	1st Class.	2d Class.	3d Class.	4th Class.
	Lbs.	Lbs.	Lbs.	Lbs.
1. Farinaceous substances, consisting of bruised or ground beans, peas, wheat, barley, or oats	5	5	10	5
2. Bran, fine or coarse	-	-	-	7
3. Boiled or steamed potatoes, mashed in a tub with a wooden bruiser	5	5	-	-
4. Fresh grains (boiled barley)	6	-	-	-
5. Hay cut down into chaff	7	8	10	8
6. Straw cut down into chaff	7	10	10	8
7. Malt dust, or ground oil-cake	-	2	-	2
	30	30	30	30

With two ounces of salt for each class. By this table it will be seen that each horse receives thirty pounds of food in the twenty-four hours, a quantity that will in all cases be found to be amply sufficient. The addition of two ounces of salt is necessary to assist the digestion of the food. Of the four classes into which Dr. Sully divides his ingredients for feeding, those two which contain the steamed or boiled potatoes are the most recommended. No food conduces more to the healthy working condition of horses than the steamed or boiled potatoes; and we may observe, with relation to this, as well as to other kinds of food, that, when the horse comes in weary and hungry, after a long day's work, it is necessary to fill his manger more copiously with the ingredients prepared for him. Dr. Sully and all the other persons who have devised improved methods of feeding agree in the practices of bruising or coarsely grinding the grain and beans, of cutting down the hay and straw, of giving no hay in the rack, of allowing salt, and of weighing each article separately before mixture, instead of adopting the fallacious guide of measurement. (*Quart Jour. of Agr.*, vol. ii p. 727.)

8454. *Road horses*, in some parts of Scotland, and more especially in the neighbourhood of Edinburgh and Glasgow, are fed on equal parts of oat-straw and hay, cut by a machine in the lengths of from one eighth to one sixteenth of an inch. The cut straw and hay so produced are intimately mixed together, and, when musty, sometimes sprinkled with a little salt and water. The drink given to the horses is water in which oats or barley have been boiled, and the grain so boiled is found to equal double its quantity of raw grain in keeping horses in condition.

8455.—6747. *Feeding horses*. As the result of an experiment tried with boiled grain, raw grain unbruised, and raw grain bruised or cut, it appears that by far the most profitable mode is to give the grain raw but previously bruised or cut. (*Trans. H. S.*)

8456.—*The ox*. "The important family of which the common ox may be regarded as typical, divides itself into three groups,—the Blountine, the Bubaline and the Taurine. The bison inhabit both the Old and New Continents, and are distinguished by round, smooth horns, and a musky odour which exhales from the skin. The buffaloes are characterised by angular horns, and a fainter odour of musk, and are natives of the warmer regions of Asia and Africa. The taurine group, comprehending the common ox and its different races, forms the most important division of bovidæ." (*Low's Domestic Animals*, vol. i p. 1.)

8457. *The varieties of the Taurine group* described by Professor Low are. 1. The wild or white forest breed. 2. The Highland breeds, the finest of which is the West Highland. 3. The Zetland. 4. The polled Angus. 5. The Galloway. 6. The Welch, the finest of which are the Pembroke. 7. The Kerry. 8. The North Devon. 9. The Sussex. 10. The Glamorganshire. 11. The Herefordshire. 12. The Alderney. 13. The Ayrshire. 14. The polled Suffolk. 15. The Falkland. 16. The polled Irish. 17. The sheeted breed of Somersetshire. 18. The long-horned. 19. The Teeswater short-horned, or Durham. (*Low's Domestic Animals*, vol. i p. 35.)

8458. *The points by which the different breeds of cattle* may be judged are given in the *Quart Jour Agr.*, vol. v, p. 185; vol. vi, p. 266, 433 and 548, by Mr. James Dickson, cattle dealer, Edinburgh, in a superior manner to anything of the kind which we have before seen in print. We can only spare room to extract a few features.

1. *The short horns*. The frame exhibits a straight level back from behind the horns to the top of the

tall, full buttocks, and a projecting brisket; in short, the form is rectangular and perfect in its kind. The colour is red, and the richest white, approaching to cream, or both colours are mixed. Limbs small and clean, like those of the race horse, uniting strength with firmness. Head small, lengthy, tapering, neatly set on a broad firm deep neck; mildly beaming eyes, thus large veiny ears, and semi-circularly bent, white or brownish coloured short horns, in a word, a symmetrical harmony, which has never been surpassed in beauty and sweetness by any other variety of the domesticated ox.

2 *The Shetland breed* are uniformly black, light red, or black and white. "They are naturally the smallest breed of cattle in the kingdom, weighing generally from 16 stones to 20 stones the four quarters, and when extra fat, from 25 stones to 30 stones. The beef is of the very finest quality throughout, being as small in the gram as mutton, the fat well intermixed, and the flavour most delicious. In fact, in point of quality, they are, without exception, the finest cattle that are bred in the kingdom. The cows are not great milkers, but the milk is very rich."

3 *The Orkney and Caithness breeds* Orkney cattle are much larger than those of Shetland, and less symmetrical shaped. They are slow feeders, and incapable of early maturity. The Caithness cattle resemble those of the Orkneys.

4 *The North Highland breed* are bred in the counties of Sutherland and Ross. They are large, symmetrical, and feed well.

5 *The Aberdeenshire breeds* are middle sized, symmetrical, generally black, and capable of being fattened at four years old to fifty or sixty stone.

6 *The Angus breed* Middle size, symmetrical, generally black, quiet, and rather slow feeding.

7 *The Fife breeds* have rather a ragged outline, and are in general symmetry inferior to many of the northern breeds. The features of the face are strongly marked, and the expression of the eye dull. They have not an aptitude to fatten at an early age, but at four or five years they feed to great substance and heavy weight.

8 *The West Highland or Kyles breed*, is the oldest in Scotland. Form symmetrical, legs short, eyes full and sparkling, colour generally black, the nearest Scotch breed in character and properties to the short horns.

9 *The Ayrshire breed* is celebrated as milkers, but the Tweed side short horn cows are now being preferred as on the whole the most profitable, they are larger, give more milk, and take up less room, and give less trouble in proportion to the quantity of milk they give.

10 *The Galloway breed* is readily known by being without horns. The head is rather large, and looks coarse, the legs are short and strong, colour mostly black. The beef, when well and long fed, is of first-rate quality.

11 *English breeds* The *Hereford* is preferred, because they show, when fat, symmetry and points the nearest in resemblance to those of the short horns. The cows are bad milkers, and the calf consumes all the milk. They pay the feeder better than the breeder. The *long horns* feed to great weights, but they are rather coarse in the bone. The *Sussex* cattle are large red, deficient in symmetry, and when fat, frequently bought by the shipping butchers while the *Herefords* are purchased by the cutting up butchers. The *Devons* have a pure rich red colour, with white horns, fair symmetry, and consequently middling quality. When fat and cut up they want that fine mixture of fat and lean so common in Scottish cattle and short horns. The *Suffolk* cattle are all dun coloured, and the cows are great milkers. Very few oxen of the duns are fed fat, the bull calves being fed for veal and the cows kept for making butter. The *Welsh* cattle have thick horns, thick coarse plain hides, and narrow backs, and altogether are a very inferior breed. Graziers and feeders out of Wales never think of purchasing them when they can find Scottish West Highland cattle.

12 *Irish breeds* There are three breeds of cattle in Ireland the *Kerry breed*, of small size, which belongs to the mountainous part of the country, a small but larger breed, to be found chiefly in the north of Ireland, and a long horned breed, to be found in the low rich plains. The cows of the *Kerry* breed are, like those of the *Ayrshire* breed, great milkers. The breed of the plains are large and good feeders, and the grain of their flesh, being coarse, stands the salt, and is therefore well adapted for the supply of the navy. The heifers of the *Kerry* breed are in constant demand, fetch good prices, and make good poor men's cows.

13 *The Isle of Man breed* is of a mixed character, combining various shapes and colours, so that, in short, there is properly no breed.

14 *The Alderney and Jersey breeds* are too delicate for the climate of Scotland.

15 *The French breeds* are not unlike the *Guernsey* breed. They are ill made, give excellent milk, get fat on the rumps, but they are always thin on the ribs, and the beef is generally of a yellow tinge. (*Quart. Jour. Agr.*, vol vi p 568.)

8459.—6809. *The points or parts by which cattle are judged* have been laid down in a masterly manner also by Mr Dickson (*Q J A*, vol v p 189), and applied to the different Scotch breeds in the subsequent volume of the same journal. The first point is the purity of breed, which is ascertained by the colours of the skin being definite, and in particular by the bald skin on the nose and around the eyes being without spots. The second point is the form of carcass, which, taken longitudinally and horizontally, ought to be that of a solid parallelogram. A third point is a full clear, and prominent eye. The next is the state of the skin, which ought to feel mellow, a feeling which can only be understood by long practice. Sheep may be judged of by merely the same rules. A refined tone in breeding can be attained in any breed by judicious care in crossing within that breed, and the true criterion of a fine bred breed is 'like producing like.'

8460. *Measuring cattle* The weight of all solid bodies can be ascertained by external measurement, but the shape of the bodies of cattle is so very irregular and so much of the internal part is hollow that none of the ordinary rules of calculation are applicable to them. Nevertheless, as it is obvious that the bodies of two oxen which are the same in size will be nearly the same in weight, tables have been formed as the result of repeated experiments, and these tables are now in general use, and found to be practically correct. "It is only by continued practice that any one is enabled to guess the weight of beasts with accuracy those persons, therefore who have only occasionally a few fat cattle to dispose of, meet the purchaser (who is in the constant habit of buying and proving his judgment by weighing the carcass when dead) upon very unequal terms, but that great inequality will be much lessened by this aid of measurement. The measurer should be a sufficient judge of beasts to know whether they are marketably fat or not, if not, the measurer will overrate them, and also something of their proper formation, so as to be capable of forming a just opinion whether they are proportionably heavier or lighter in their fore-quarters than in their hind quarters, and thus making such necessary allowance in computing the weight from the sliding rule, or from the tables in the third edition of *Hillgard's Practical Farming and Grazing*. The method of measuring is to put a string or tape round the beast, just behind the shoulder-blade, and take its circumference in feet and inches, that is called the girth then with the tape or string measure from the fore part of the shoulder-blade bone, along the side of the back, over the hip to that bone under the tail which plumbs the line with the hind part of the buttock this is the length. Opposite these figures in the book or scale is the weight of the carcass in stones of 8 lbs and of 14 lbs, when separated from the offal. Thus — girth 6 ft 6 in by 5 ft 8 in length, gives 37 stones 3 lbs of 14 lbs., 100 stones of 8 lbs; which is equal to 10 score per quarter. — 7 ft. 10 in. by 5 ft. 10 in gives 55 stones 10 lbs. of 14 lbs; 150 stones of 8 lbs., equal to 15 score per quarter. The girth is easily taken; but the length requires great care to take it correctly. The beast should stand quite straight whilst measured, and the exact part of the shoulder-blade should be felt" (*Journ A E*, vol ii p 328.)

8461.—6862. *Feeding horned cattle on raw, or on steamed or boiled food* Though boiled corn is found

to be doubly nutritious to horses, yet, from a number of experiments made by practical farmers, with a view of obtaining the premium of thirty sovereigns offered by the Highland Society of Scotland, it has been given as an opinion, that, in the case of the ruminating animals, no advantage whatever results from cooking their food. (See *High Soc Trans.*, vol. x. p. 253).

8462.—8556. *On the treatment of cattle in winter.* An excellent paper on this subject will be found in the *Quarterly Journal of Agriculture*, vol. li p. 328—341. Some difference of opinion exists among agricultural writers as to whether young growing cattle ought to be fed, or pampered, as Dr. Coventry calls it, with rich food, or supplied with abundance of coarser food. The writer of the article referred to inclines to the former opinion, on the principle of its being the farmer's interest to treat his cattle in such a way as shall enable him to bring them soonest to market. Coarse food, he says, ought not to be found on a well-cultivated farm. Straw and water, in an agricultural sense, are not food at all. Straw given to cattle, with a view of being consumed as their only food, is just so much straw wasted, and time lost, in the forwarding of their condition. A limited supply of turnips will keep cattle alive and may prevent them from falling off in flesh, but it will never bring them to a state of fatness, though they were to eat in that manner for any length of time, whereas a moderate quantity beyond this limited portion would constitute abundance. Scanty food renders cattle uneasy; whereas food in abundance renders them contented and able to endure every inclemency of weather. A farmer ought neither to rear nor purchase more cattle than he has food sufficient to keep in affluence, for though this might lessen the number, both on individual farms and in the country generally yet the quantity of butchers' meat brought to market would be greater, and its quality better, than it now is. Hence on the score of profit to the farmer, and ease and comfort to the cattle themselves abundant nourishment ought to be given to the latter from the earliest period of their existence, until their growth is complete. Cattle may be fed in houses, and tied to stakes, or in what are provincially called "hammels" which are small open courts, with an open shed for shelter on the north side. Twenty calves, or ten yearlings, may be put into one of these hammels. A hammel with a shed seventeen feet in width and fourteen feet in depth, with a court twenty-one feet by seventeen feet, will contain three large oxen, or four smaller-sized cattle. Every hammel must be supplied with pure water at the command of the cattle. Before the cattle are put into hammels or byres, the floors ought to be well littered, so as to form a sort of drain to carry off the urine to an underground tank, whence it may be pumped up for use. Cattle fed on turnips eat very little straw, and therefore the first thing that should be given to them in the morning is turnips the troughs for holding them having been previously cleaned out. In the byre the first thing to be done in the morning is to draw the dung from behind the cattle into the urine canal, and while the cattle are eating their turnips the dung can be wheeled to the dunghill. Fresh straw, for fodder, may be given about the time that the turnips are eaten up, a small quantity being placed before each beast in the byre, and in the racks under the sheds of the courts. Oat-straw is found to constitute the best fodder for cattle, potato oat-straw is, perhaps, better than that of the common oat, as the former is always cut down before it is quite ripe. Hay is no doubt better than any kind of straw and those who have abundance of that desirable fodder may give it ungrudgingly to cattle, in the certainty of being soon repaid its value. Turnips should be given again about mid-day, and about three o'clock in the afternoon the mangers should be cleared out, and straw or chaff given. In the byre after this allowance is eaten up, the mangers should be cleaned out before giving another foddering of straw. A trowel will be found a handy instrument for this purpose. At the hammels the last foddering of straw can be given any time after the last allowance of turnips, which should be ample, as the cattle will come backward and forward to them even in the dark and in moonlight they will feed as well as during the day. The calves should be served with turnips immediately after the feeding-beasts, and the year-olds can also get a few at this time, to complete their day's allowance. Between the allowances of turnips, litter should be sprinkled in the byres and hammels, to induce the cattle to lie down after repletion, to chew the cud, which they will invariably do. At eight o'clock at night the byres should be looked at with a light, and the cattle supplied with the fodder necessary and their beds made comfortable for the night, by drawing back any dung that may be on them, sprinkling some more litter, and shaking it well up with a fork. At the hammels, if it is moonlight, some more turnips should be thrown, even at this time of night into the mangers. During the day the water troughs should be all kept full of fresh water, and any filth that may have been blown into them by the wind should be removed. When the frost becomes so severe as to harden the turnips, they should no longer be brought from the field, but from the store formed of them in the beginning of winter for the purpose of supplying the cattle with fresh turnips during the continuance of frosty weather, nor should any more be taken even from the store than what can be consumed in a day. Frozen turnips may be thawed by being placed in a tub of cold water, but this is a very tedious and troublesome mode of obtaining fresh turnips in frosty weather, compared to the excellent practice of storing a considerable quantity in open weather.

8463. *In the feeding of cattle.* It is of the utmost importance that the man who has the charge of them should be very attentive to his duty, and in particular that he should be exact even to a minute, in supplying them with turnips. Cattle know perfectly well when the time arrives for a fresh supply even though the mangers in the hammels may not be empty which they should never altogether be. When they are supplied with food at irregular times, they will either be always craving it, or become careless about it, and their uneasiness arising from frequent disappointments will prevent them from feeding so pleasantly and speedily as when their food is placed before them at exact periods. When the man thus regulates his different works by time, he will find leisure moments during the day to perform many necessary acts, which, though they may appear of little importance in themselves, nevertheless contribute greatly to the appearance of neatness and comfort in the farm-yard and its inmates. Thus, he might spread the stable-litter along the edge of the turnip-troughs of the year old cattle, to keep any turnips clean that may have been pulled over by the beasts, for, when cattle are first put up to feed, the freshness and tenderness of the leaves induce them to eat these first and in the anxiety of each to obtain another fresh bite, many turnips are necessarily turned over. The man can also shovel and scrape together any mud about the causeways, and the places on which the turnips have been laid down from the field. He can frequently examine the skins of the cattle, and give immediate notice of any eruption, for cattle, after being a month or six weeks on turnips, get very itchy in the skin, the violent rubbing of which often causes ulcerated spots to break out but which can easily enough be cured at first, by an application of a decoction of tobacco, with a little spirit of tar. He should rub those parts of the body which they cannot easily get at to lick with an old currycomb and scrape off any dung that may adhere to the hair in the hinder and under parts of the body, with a large blunt knife and this attention is more necessary at the beginning of the season than afterwards, as the freshness of the stems, and the juiciness of the roots of the turnips and the greediness which all cattle evince for them at first, often cause a looseness in their bowels. He should observe the first indication of lice in their skins in the early part of the spring, when these may be easily destroyed, by applying to the affected parts a solution of mercurial ointment; but, if neglected, they will cause much uneasiness to the cattle, making their hair peel off, and exposing to view an unsightly skin, and he may handle them frequently on every part of their body, as they are very fond of being handled when they are rising in condition, and it is also serviceable to familiarise them with man, as cattle, when they have been accustomed to be handled, will stand better, and show themselves more satisfactorily to the buyer. There is something so winning in a gentle disposition in powerful animals, caused by good treatment, that a buyer will prefer them, when they have to be driven a distance upon the road, and the butchers in the neighbourhood will also prefer them, as they will walk peacefully to the shambles, without the risk of being raised to a frenzy. All these constitute the minutiae of the business of feeding cattle on turnips in winter, and, trifling as they

may appear, attention to them will be amply repaid, in the shape of prime beef and docile cattle. The whole may be easily accomplished by any man who regulates his movements by the watch; and the man having the charge of cattle in winter, who will do this whether he is seen by his master or not, is an inestimable servant.

8464. *The quantity of turnips which feeding cattle will consume*, as stated by most writers, is about one ton every week, for an ox of from sixty to seventy stones, or about one acre of a fair crop of turnips in six months. Thirty-three double-horse cart-loads of turnips, each weighing from sixteen cwt. to eighteen cwt., are a good crop on light sharp lands.

8465. *Time of putting up to feed*. If the second growth of grass has continued fresh till the latter part of autumn, cattle may be soon enough put up to feed by the 1st of November; but if the grass fall sooner, which it will in most seasons do, the middle of October is late enough for putting them up to feed. White globe turnips are an excellent juicy food for cattle till the commencement of the new year, after which should follow the yellow or green tops, for two months longer, and then the Swedish turnips will finish the season. If the Swedish turnips have been stored up before the second growth of the stem has made its appearance in spring, they may be taken out quite fresh till the beginning of June. Since the cultivation of the potato has increased so rapidly, many people feed their cattle on it in spring either wholly or mixed with turnips. When cattle are fed on potatoes, attention ought to be paid to them after feeding, for fear of internal swelling. When observed at first, the swelling may be allayed by pouring down the throat a bottleful or less of common whale oil, which will check the fermentation, and operate as a purgative. Should any of the young cattle or the feeding beasts in the byre be choked with a piece of turnip, for those fed in hammels never or very seldom do so, the best expedient is to use the probang at once, rather than to permit the throat of the poor animal to be squeezed, and consequently inflamed, in attempting to push the piece of turnip up and down. The probang may be used with great success, by causing the animal to be forcibly held by superior strength, with its neck and mouth stretched forward, and while one is pushing the instrument gently down, another is directing the end of it down the gullet on the outside of the neck. When the piece of turnip is pushed down into the stomach, let the instrument be gently drawn out; and if, during the operation, the animal forcibly twists its head about, the instrument should instantly be let go. Feeding cattle will eat very little straw; but they ought to have abundance of litter at all times.

8466. *Comparative merits of feeding cattle in hammels and byres*. "Our decided predilection is in favour of hammels. In them the cattle are at perfect liberty to roam about, if disposed for exercise: they are exposed to all the sunshine there may be in a winter day; and the very rain which falls on their backs tidulates the skin, and causes them to lick and clean themselves; they are comfortably warm in their sheds among an abundance of straw in the coarsest night, and cattle will never suffer from cold, when they have a comfortable shelter to which they can repair at will; they can come and go to their food whenever they please, night and day, and their meat being constantly in the open air, it will be always fresh and sweet; and their feet and hair, when they come to travel, are quite able to bear the hardness of the road and the coldness of the air. These are all advantages which no byre can equal. Nor are the hammels so expensive in their original erection as many represent them to be. We have seen a range of them consisting of five divisions, capable of feeding twenty large oxen, erected for 20*l*.; but these had no regular roof. The roofing of all buildings is the most expensive part of them. The roof of those to which we refer, consisted of trees laid across as beams, about a foot asunder, the space between them being filled up with the branches of the spruce fir and Scotch pine. Such a place was a choice one for stacking pease or beans upon. To this purpose it was often appropriated; or it was covered with straw, roped down, which was used as bedding for the cattle in the first part of the succeeding season, when fresh straw was put in its stead. In the hammels which faced the south, the cattle were well fed and comfortably lodged; and no byre could have afforded so much accommodation at the same expense." (*Quar. Journ. Agr.*, vol. ii. p. 241.)

8467.—8978. *Milk is preserved from becoming acid by the addition of any alkali*; because, when milk ferments, it develops an acid, which the alkalies neutralise. Hence alkalies prevent the curdling of milk. Alkalies applied to curd will turn it into milk: they are not unwholesome, but in large quantities give the milk a disagreeable flavour. (*L' Agriculteur-Manufacturier*, Mai, 1831.)

8468.—7008. *A curd-breaker for skim-milk cheeses* (figs. 1181. and

1182.) has been invented by Mr. Robert Barlas, of Gilmour Place, Edinburgh. It consists of a hopper of wood (fig. 1181. a), seventeen inches and a half by fourteen inches on the top, and ten inches in depth; and a cylinder of hard wood six inches and three quarters (b) in length, and three inches and a half in diameter. The cylinder is studded with square pegs made of hard wood, each a quarter of an inch in the side, cut square at the ends, and projecting three eighths of an inch. There are eight teeth in the length, and fifteen in the circumference, of the cylinder, 120 teeth in all. It revolves on a round iron axle twelve inches

in length, and is moved by the crank handle (d in fig. 1182.); c c are two wedge-shaped pieces of hard wood,

made to fill up, in some degree, the space between the side of the hopper and the cylinder. These pieces rest on a slip of wood nailed to the lower rim of the hopper, to keep them in their place. The face of these is studded with nine teeth of hard wood, similar to those on the cylinder, at opposite sides. The stand (e) (fig. 1182.) can be made of any length,

to suit the breadth of the tub into which the curd is broken. The implement is used in this manner:—Place over it a tub, heap the hopper (a), with curd, and, on turning the winch (d) in either direction, the curd will fall, broken quite small, into the tub. While one hand is moving the machine, the other can press the curd gently down into the hopper. As cleanliness is a matter of the greatest importance in cheese-making, the internal parts of this machine, being loosely put together, can be easily taken to pieces to clean. The cylinder axle rests on two hard wooden blocks (f, fig. 1182.), one on each side, which slip out of their groove. They are held in their working position by the thumb-catch

(g), such flush with the bottom of the stand (e), one over each block. The wedge-shaped pieces (c, e, Fig. 1181) come out. To prevent the curd working out of the sides of the axle the cylinder is set a little at both ends into the sides of the hopper. The dotted lines in Fig. 1182 will give an idea how the internal part of the machine is constructed. Only one tooth is represented on the cylinder by the dotted lines, to show the position of the whole (Quart Jour Agr vol iv. p. 685.)

1183

is also placed on this axis, but turns freely round it. In the forked part of R there is a nail or click, c (better seen at c\*), which, turning on the pin K, may be made to engage in the notches of the ratchet-wheel R. By means of this arrangement, when I is raised up and G engaged in R the axis N, and its pinion, will be turned round with great power on depressing the end I of the lever, and by alternately raising and depressing I, any degree of pressure required may be given to the cheese, after which, if it be wished to continue the pressure and to follow the gradual shrinking of the cheese, the lever is to be raised above the horizontal position, and the weight W hung on which will cause it to descend as the cheese yields. By inserting the pin P, this effect may be discontinued, and the farther descent of a prevented (Highland Soc Trans vol x p 52.)

1184

8470 The pneumatic cheese press (figs 1184 and 1185) is the invention of John Robison Esq., Sec R.S.E. When of full size, this press may consist of a stand about three feet high on the top of which may be fixed a tinned copper or zinc vessel, of any required capacity (say eighteen inches diameter, and eighteen inches deep) to contain the prepared curd. This vessel should have a loose bottom of ribbed work covered with wire-cloth, from under which a small tube, nearly twelve inches long should communicate with a close vessel, capable of containing all the whey which may be drawn from the curd in the upper vessel. At one side of the stand there may be a small pump-barrel of about seven inches deep, from the bottom of which a suction pipe should terminate at its upper end in a valve opening upwards, and a piston, with a similar valve, should be placed in the pump barrel and be worked by a jointed lever, as shown in the model. The process is to be conducted as follows:—The curd being prepared, and salted in the usual way, a cloth is to be put over and into the upper vessel, and the curd put lightly into it, except round the edges where it should be packed quite close to the sides of the vessel so that no air may pass that way, the pump handle is then to be briskly worked for a few minutes on which the pressure of the external air will force the whey to run down the tube into the whey-vessel, when it ceases to run, a few strokes of the pump may be repeated.

The cloth and its contents are then to be lifted bodily out of the curd-vessel, and to be put into a mould of close wirework, with a weight placed over it until it becomes firm enough to be handled. The mould should stand on a sparred shelf (a shelf made of laths like a bacon rack) to allow the air free access to it on all sides of the cheeses. In Fig. 1184, a is a vessel containing the curd; b, a vessel for containing the whey; c, a tube communicating from a to b, d, an air pump for exhausting the air in b, e, tube communicating from d to b, f, a tub for letting off the whey from b. Fig. 1185 is a false bottom for the vessel a; g, wood frame, h, wire-cloth. (Highland Soc. Trans., vol x p 200)

1185

8471. *Alwood's newly invented churn* (fig. 1186), "being made entirely of block tin, the necessary degree of temperature can be given to the cream, by placing it in a pan of cold or hot water, which ensures the butter coming in ten or twelve minutes at all seasons of the year. The simplicity of its construction, and the facility with which it may be cleaned, are no inconsiderable advantages over those now in common use. The great advantages will be found in the winter; but in the heat of summer, the placing the churn in cold water will be the means of hardening the butter." (*Johnson's Agr. Imp.* for 1842, p. 8.)

8472.—7010. *A stone-ware churn*, of which fig. 1187 is a perspective view, has lately been invented, or brought into notice, by Mr. Daniel Chambers, of Carey Street, London. In form, and in the manner of using, it is in every respect the same as the patent box-churn, figured in page 1040; but the great advantage of the present invention is, that, being made of earthenware, it is much easier kept clean and sweet than when made of wood. The size of

that of which we have given a figure is the smallest that is made, and it will churn so small a quantity as half a pound of butter at a time. As this churn, from being made of earthenware, is rather too heavy

for being lifted up and emptied, there is a small hole on one side near the bottom (indicated in the figure), to let off the butter-milk; which hole is easily stopped with a common cork. The lid has a rebate, as shown at a in the figure, for the purpose of preventing the milk from splashing over during the operation of churning. We have much pleasure in noticing this invention, because it will not only greatly contribute to cleanliness, and to the sweetness of the butter produced, but also to lessening the labour of the dairy maid in scalding and scouring. (*Gard. Mag.* 1839, p. 144.)

8473.—7086. *New Stilton cheeses* may be made to acquire the flavour and appearance of old ones, by inoculating them with portions of the old, containing blue mould. The little scoop which is used in taking samples of cheese, affords a ready means of performing the operation, by interchanging ten or a dozen of the rolls which it extracts, and placing them so as to disseminate the germ of the blue mould all over the cheese. A new Stilton cheese treated in this way, and well covered up from the air for a few weeks, becomes thoroughly impregnated with the mould, and generally with a flavour hardly to be distinguished from the old one. (*Highland Soc. Trans.*, vol. xi. p. 233.)

8474.—7093. *Schabziger cheese* is flavoured with the bruised seed of *Melilotus schabziger*, or blue

melilot, which smells exactly like a pigsty. (*G. C.* 1842, p. 381.)

8475.—7115. *The varieties of the sheep described by Professor Low*, are:—1. The Zeland and Orkney breeds; 2. The breed of the higher Welsh mountains; 3. The soft-wooled sheep of Wales; 4. The breed of the Wicklow mountains; 5. The Kerry; 6. The forest breeds of England; 7. The black-faced heath breed; 8. The Cheviot; 9. The old Norfolk; 10. The old Wiltshire; 11. The Dorset; 12. The Merino; 13. The Ryeland; 14. The South Down; 15. The old Lincoln; 16. The Romney Marsh; 17. The older long-wooled breeds of the inland districts; 18. The Cotswold; 19. The new Leicester. (*Low's Domestic Animals*, vol. ii.)

8476.—7184. *Management of the fleece in Australia*. In order to assimilate the Australian wool as much as possible with the German, in preparing it for market, the fleeces should not be broken, but merely divested of the breech and stained locks, and so assorted or arranged that each package may contain fleeces of the same character as to colour, length of staple, fineness of hair, and general quality.

8477. *If the washing* has been performed at the same time and place, and with an equal degree of care, the colour is likely to be uniform, and it will then only be necessary to attend to the separation of the fleeces as to length, fineness, and general quality; but if a large grower has flocks of different breeds, and fed on different soils, care should be taken that the fleeces be separated, first, as to colour, and then, again, as to length, fineness, &c.

8478. *Packing*. The fleeces, being assorted as already suggested, should be spread one upon another, the neck of the second fleece being laid upon the tail of the first, and so on alternately to the extent of eight to ten fleeces, according to their size and weight. When so spread, the two sides should be folded towards the middle, then rolled together, beginning at each end, and meeting in the centre; and the roll or bundle, so formed, should be held together by a slight packthread.

8479. *The bagging* should be of a close, firm, and tough nature. The material hitherto most generally used has been sail canvass, which very ill resists bad weather on a long voyage, and, when received here, even in favourable condition, is so dry and crisp, that it will tear like paper. A thicker, twilled, more flexible, and tough material would be preferable. The size and form of the package may be in length about nine feet, and in width four feet, sewed up on the two long sides, and at one end, the other end being suspended with the open end upwards to receive the bundles made up as before directed, which are to be put in one at a time, one of the flat sides of the roll or bundle being put downwards, and so on in succession; and the whole being well trodden down, until sufficiently filled for the mouth to be closed. This is the German mode of packing, but it is doubtful whether packages of the dimensions that have been hitherto sent from the two colonies may not be more convenient for so long a voyage.

8480. *The operation of screwing* should be discontinued where it has been practised; as the pressure by the screw, and the remaining compressed during the voyage, occasions the wool to be caked and matted together in a manner that is highly prejudicial to its appearance on arrival. The practice, also, of winding up each fleece separately, and twisting a portion into a band, is productive, in a minor degree, of the same prejudicial effect; and it is to avoid this that the making German bundles of eight or ten fleeces is suggested. (*Hobart Town Courier*, Jan. 8. 1834.)

8481.—7318. *Feeding sheep*. It is well known, from the discoveries of the first chemists, that turnips are deficient in nitrogen, and that all animals require a portion of it for their healthy nourishment. Clover and meal contain, besides other nourishing substances, a sufficiency of nitrogen for the supply of animal flesh, and their addition greatly increases the fattening qualities of turnips; much of the juice of the turnips remains undigested, and is voided without any change, when they are the only food of the sheep, which more nitrogenous food would enable the stomach to decompose: at least such is the prevailing theory; and it is very plausible. Experiments and accurate observations alone can substantiate it, or refute its truth. (*G. C.* 1843, p. 132.)

8482. *Feeding sheep in a shed*, though they consume nearly one fifth less food, made above one third greater progress. (*J. W. Childers, Esq.*, in *Journ. A. E.*, vol. i. p. 169.) Subsequent experiments exhibit still greater advantages, particularly during the winter months. By giving the sheep cake, and a

Hills crumbed barley, they may gain from 23 lbs. to 40 lbs. a head in the course of ten weeks, at that season. Much of the success depends on having a boarded floor, which prevents the sheep from taking the foot rot. (*Ibid.* p. 410.)

8483. *A rain-proof feeding trough for sheep has been invented by a farmer of Fife-shire, Mr. Bell, near Cupar, and is described and figured by Mr. Bulst.* It is an adaptation of the common pheasant feeding box to the sheep trough with the addition of a simple application of the bird cage watering glass. (*See Quart. Jour. of Agr.*, vol. xi. p. 115.)

8484.—7483. *The varieties of the hog described by Professor Low, are:—1. The wild hog; 2. Siamese or Chinese breed; 3. The old English breed, and 4. The Berkshire breed.* (*Low's Domestic Animals*, vol. ii.)

8485.—7515. *Preparation of food for swine.* Mr. Bolton, who has fattened swine to an enormous weight, has the following observations on the subject in the *British Farmer's Magazine*, vol. vii. We consider them worthy of quotation, with a view of impressing on the mind of the reader the importance of fermenting food for this class of animals:—"I always feed my pigs on sour food, which I have invariably found to feed them faster, and to make the flesh firmer and whiter, than food given in any other state. The following is my method of preparing it:—As soon as the potatoes are steamed, I have them, while quite hot, beaten to a pulp, and mixed with bran, in the proportion of twenty-eight pounds of bran to a sack (280 pounds) of potatoes, and this mixture is put into a vat for ten or twelve days, till quite sour; this food makes the pigs fat enough for porkers or small bacon. When I require them more than commonly fat, I begin with fifty pounds of barley flour, instead of the bran, to each sack of potatoes, gradually increasing the quantity of flour till it amounts to half the weight of the potatoes; when the quantity of flour is greater than the moisture of the potatoes will absorb, I add a sufficient quantity of water to make it into a thick paste: I never give it until it has fermented."

8486.—7516. *Pigs on Hampshire are frequently washed and rubbed with a hard brush, which is found greatly to improve their condition, and is one of the principal causes of the bacon of that country fetching 2d. more per pound than that of any other.* (*G. C.* 1842, p. 351.)

8487. *A description of Mallet's improved apparatus for cooking fodder for cattle by steam.* The simplest form of apparatus for this purpose, usually met with, consists merely of a common open boiler, over which a tub, with its bottom perforated, is placed, and the junction rendered steam-tight by what is called a water-valve or water-lute joint; that is to say, by the lower edge of the tub projecting below its bottom, into an annular space round the upper edge of the boiler, filled with water. The tub is filled with the vegetable matter to be cooked; and the steam rising through the perforation of its bottom, from the water beneath (a fire having been lighted under the boiler), prepares it. This apparatus, excellent as it appears from its simplicity, has many disadvantages. The tub requires to be lifted on and off, by means of a crane, if of large size; a separate boiler is required for each tub; there is no mode of regulating the supply of steam, but by damping the fire, or urging it; and the boiler, to be supplied with the water spent in steam, needs the tub to be previously lifted off. Added to all, the boiler must be circular, and, therefore, of the worst possible form for economy of fuel. The next form is that in which several steaming vessels are supplied from one boiler, which may be of any form. Each of these vessels consists of a tub, as before, with a perforated bottom, and close but moveable cover, which is placed on another shallow tub, with a close bottom, into which the steam from the boiler is conducted by a pipe from the boiler; the junction between the two tubs being made good, either by three or four thicknesses of felt, or by a gasket; a cock regulates the admission of steam to each lower tub, and a crane is provided, which commands the whole range, and lifts them on or off. The arrangement answers tolerably well, but has some inconveniences. But a comparatively small surface of the potatoes or other fodder is exposed to coction. The crane for lifting off the tubs, when each is capable of containing from four to six barrels of potatoes, requires to be a strong and rather costly piece of work; and the consumption of time and labour in lifting on and off, filling and emptying those tubs while hot, is very great, whereby a considerable loss in fuel accrues. All these considerations may be of small importance where the quantity of fodder cooked is small, and therefore the cost of labour and fuel slight; but where a large stock of cattle is to be fed with cooked food, and the apparatus is therefore nearly at constant work, every consideration of facility and economy becomes in the highest degree important. Accordingly, the following train of apparatus was designed for a gentleman, who is not only an extensive rearer of cattle, but one of the most distinguished agricultural improvers in Ireland. It is conceived that it embodies most, if not all, that can be wished for the purpose. Fig. 1188. is a longitudinal section of the boiler, which is cylindrical, and

four times its diameter in length. Witty's patent gas-furnace is applied to it; a is the inclined plane; b, the fire-bars; c, the dead plate; d, the ash-pit. The flame and heated air passes under the boiler through the bottom flue, f, thence through the tubular flue, g, right through the body of water in the

\* Robert La Zouche, Esq., of Harrington.

boiler; at the extremity of which it goes off, right and left, through two lateral flues, which join at *k*, and go into the stack or chimney: *i* is the feed head, supplied either from any sufficiently elevated source, or by a pump; it is adjusted to supply the boiler at a pressure of 14 lb. to the square inch: *k* is the safety valve, loaded to the same pressure; this steam from *k* blows into the flue; *l* is the man-lid; *m*, a whistle, for the purpose of giving notice when there is a deficiency of water in the boiler, should such ever take place; boilers upon this construction being much more liable to injury in this respect than those which have no internal flues, *n* is the steam-pipe and stop-valve, which is connected with the steaming vessels. Fig 1189 is a cross section of the boiler: the same letters refer to both figures. The top part of the boiler, above the masonry, is covered with a wooden jacket, one inch thick, and supported by segments of angle iron, at an interval of one inch and a quarter from its external surface; and for the same reason the walls of its setting are all built hollow. Fig 1190. is a side elevation of the steaming vessel for cooking potatoes, carrots, parsneps, turnips, &c. or other such things; of which fig 1191 is a cross section, through the centre of its length: the same letters refer to both. *a* is the external cylinder or outer case of the vessel, formed of oaken staves one inch and a half thick, hooped together, and having a close end, staved in at the end *b*. The other end is closed by a moveable lid (*c*) of wood, fastened by cotters driven through

two links formed in projections from the adjacent hoop, and made steam-tight by a gasket, soaked in bees' wax and tallow, it is capable of being very readily put on or taken off. In the lower segment of

the cylinder, an arched wooden false bottom, *d*, is placed, stiffened by slight cross ribs of cast iron, and perforated full of holes five eighths of an inch in diameter; above, and supported by this, the matters to be cooked are placed until they quite fill the cylinder. The whole thing is hung upon two gudgeons or journals, *e e*, passing through the centre of gravity of the cylinder, when loaded, so that, by the arrangement about to be described, either end of it may be elevated or depressed. One of these journals is hollow, and immediately connected with the steam-pipe from the boiler by a stuffing-box, *f*, so that the steam enters the bottom of the cylinder through this journal and the curved pipe *g*, the former having still free liberty of motion. Both journals move in brasses, resting on strong diagonal framing, *h h*, bolted down to a mass of masonry. *i i* are two wrought-iron links, connected by joints with the hoops of the cylinder at top, and with the extremities of the equibrachial lever *k*, the centre of which consists of a Y shaft, *l*, supported by two or three slight frames, *m m m*, and having the long vertical lever *s* keyed on it at one end. These frames are bolted to proper timbers in the

floor of the loft above. Now it is obvious that, by means of the vertical lever *s*, either end of the cylinder may be elevated or depressed, and that the natural tendency of the whole system, when at rest, will be to remain horizontal. From the bottom or side of the cylinder at *o* proceeds a small tube, to take away the condensed steam, so made, that it shall permit the water to pass, and yet be steam-tight, and also that it shall remain vertical, whatever be the position of the cylinder. This is shown enlarged in fig 1193. The upper end of the tube works in a steam-tight joint, *a*, like the pin of a common cock, but made so that there is a free passage through in all positions of the tube. The screw tail of this joint is secured into the bottom of the cylinder by a brass nut and felt washer, the point being placed with its axis of motion at right angles to the axis of the cylinder. The lower end of the tube *b* (shown only in part) consists of an inverted siphon, the returning limb of which is of such a length that the column of water retained in it is equal in pressure to the density of the steam in the cylinder. The greatest part of this tube hangs freely in a square aperture, below the level of the floor in fig 1189, and 1190, where it is connected with a small sewer to take away the water. It is evident that, when the cylinder is moved, the tube will rise and fall vertically in the hole or upright trunk in the floor. Now for the mode of working this steaming vessel. The steam being up in the boiler, and the lid *c* removed, the end *c* of the cylinder is elevated to an angle of about 40°, when it comes just under a large wooden shoot or hopper from the loft above, close to which is placed a sliding machine, for dividing mangold wurzel, turnips, or other large roots requiring to be steamed, from whence they drop direct through the hopper into the cylinder until it is full. Potatoes are either shot direct from a cart (if the situation permit of it) through the hopper, or from sacks from men's shoulders, into the cylinder. When it is full, the lid *c* is put on, and cotted tight, the cylinder again placed horizontally, and the steam admitted. When the steaming is complete, a low capacious truck, or a large square basket on wheels, or any other convenient receptacle, is brought under the end *c*; the lid is removed, and the end *c* is now depressed sufficiently to cause the vegetable matter to fall out; the steam being previously shut off - the operation is then complete. The false bottom is now to be withdrawn, and it, together with the inside of the vessel, scraped and washed: the former is only necessary when potatoes are cooked in it. The objects proposed in this arrangement

are, perfect ease in filling and emptying; without the necessity of handling either the heated vessel, or food; nearly a maximum capacity with a minimum cooling surface to the vessel; perfect staunchness, durability, and readiness of examination and cleansing of the interior. If there be no other elevated supply of water to the steam kitchen, a pump should be fixed in it, both to supply the boiler and to wash the vessels; potatoes, especially, leave a kind of slime upon the inside of steam tubes, which soon putrefies. It is said the cattle are sometimes choked by small potatoes, which are not sufficiently steamed; this might be prevented by the addition of a pair of rollers, into the hopper of which the cylinder might discharge its contents; and they would bruise all to a given size, and deliver into the truck before mentioned.

Fig. 1192. is a side elevation of the cylindrical vessel for steaming hay, chaff, bran, oats, clover, &c. It is of a much larger size than the cylinder for steaming more solid matters; and, therefore, is not made of wooden staves, but of iron plate riveted together like a steam boiler. Fig. 1194. is a cross section of the same: the letters of reference apply to both figures alike. The cylinder is supported on four vertical frames of cast iron, *a a*, properly connected by diagonal stays; one end of it is riveted in, and through it the steam-pipe *b* enters. The other end is moveable, and closed by a circular lid or cover, also of boiler plate, secured by six cotter bolts, as shown in elevation, Fig. 1193; it is strengthened round its edge by a ring of two inches and a half angle iron riveted on, and is externally slightly convex: *c* is the convex false bottom, formed of sheet iron one eighth of an inch thick, punched full of round holes three tenths of an inch diameter, and stiffened by ribs of T iron, riveted to its lower side: *d d* are two siphon tubes for emission of condensed water, as before described: *e* is a man-lid for the purpose of filling in chaff, &c., or other such matters. The large end lid has got a counterbalance weight attached to the chain *f*. The whole of this cylinder, and all the steam-pipes, are lapped over with slight haybands, which are lapped over with thick felt or dreadnought; and this, lastly, is sewed tightly over with strong sail

canvass painted. This mode of uniting, as a coating, several bad conductors having different conducting powers, is found to resist the passage of heat much more effectually than an equal thickness of

even the worst conductor of the three. This fact, which, I believe, has not been hitherto noticed, will at once suggest to the scientific reader some striking analogies to the passage of sound through media

of different density; and which, indeed, caused the arrangement which has been described to be adopted. It will thus be seen that this second cylinder is very similar in its general construction to that first described, except that it is not moveable; which, from its magnitude, would be inconvenient, and it is unnecessary for either hay or chaff, &c. Now of the mode of working it. In the left above, immediately over the man-lid *c*, is placed a chaff-cutter, and also a bean and oat crusher, which both discharge by separate hoppers into the cylinder. The end lid having been put on and cottered up steam-tight, the vessel is thus filled with the desired material, which is spread uniformly with a fork through the man-lid. Steam is then turned on; and, when the operation is complete, the end lid is loosed and thrown up by the aid of the counterbalance above the cylinder end, and the contents drawn out by forks, or by a large but light and slender instrument like the worm of the ramrod of a gun. Before being used the first time, the inside of this vessel is given a coat of drying oil and copal varnish mixed, which prevents subsequent oxidation. The general intent of the whole of the apparatus is to save labour and fuel, which it does effectually; and that portion of it for cooking potatoes is now about being erected in the new gaol of Mayo, the largest in Ireland. In some few cases, where the extent of the

apparatus would be very great, and labour dear, it might be advisable to connect a small steam-engine with it, working from the same boiler, to pump water, slice turnips and mangold wurzel, cut chaff, and

1194

1195

bruise oats and beans, &c. Where a high pressure steam-engine pre-exists on a farm for other purposes, the waste steam from it may be made fully available for steam-cooking apparatus, which thus would cost nothing, it requires, however, a particular adaptation, in order that the power of the engine may not be reduced, by driving the steam through any considerable resistance. Occasionally, but rarely,

fluids may require to be boiled by steam, as starch for pigs, or wash for calves: for these, another form and construction of vessel altogether is necessary. (*E. Mallet.*)

1196 (§ 8489.)

8488—7431. Warmth is strongly recommended for promoting the health of poultry. Cold, it is found, either produces inflammation of the lungs, or pulmonary consumption. Heat constantly prevents this, and alleviates the disease when it has taken place. (*Annales des Sciences Naturelles*, as quoted in *Quart. Jour. of Agr.*, vol. II. p. 563.) Warmth, also, makes fowls lay. Every housewife knows that eggs are most abundant in warm weather; and all country housewives know that the only way to make hens lay in cold weather, when eggs are dear, is to

feed them well and keep them warm—the latter being of very nearly as much importance as the former. Some excellent observations on the subject of rearing and feeding poultry will be found in our *Ency. of Agric.* 1835, to 1839, and 1856.

8489.—7684. *The phenomni-fender* (*Ag.* 1196.). This ingenious invention is manufactured of iron by Messrs. Cottan and Hallen, and seems the best utensil of the kind that we have seen. There is one of tin, lighter and cheaper (see *Gard. Mag.*, vol. v. p. 589.), sold by Messrs. Baily, 273. High Holborn, and by West in Oxford Street, but it is by no means so durable.

8490.—7681. The mole may be extirpated without the use of traps by digging up the mole hills in the course of the month of March, which is the breeding season. In order to give an idea where the mole's nest is to be found, reference may be had to *Ag.* 1197. and 1198.; the first of which is an underground

1197

1198

plan, or horizontal section of a mole-hill, and the second a vertical section. In both these figures, *a* is the mole's nest; *b*, vertical tubes or runs, by which the mole ascends with the soil which it has excavated from the place forming the nest, in order to raise a hill over it to protect it from the rain; *c c* show the surface of the ground; *d*, a tunnel above the surface of the ground, in the soil of the artificial hill; *e e*, the common run of the mole extended to an unascertained length on every side; *f*, line indicating the base of the hillock. After removing the hill, and destroying the young moles, by waiting a little without making the least noise, the parent will make her appearance and may be also destroyed. (*L'Agrologue*, vol. i. p. 220.)

8491.—7632. *A mode of catching rats* by baiting the traps with ground pale malt scented with the oil of caraway seeds, and which is said to be very effective, will be found described, at great length, in the *Quart. Jour. of Agr.*, vol. II. p. 319.—331.

8492.—7684. *Wire worm*. The refuse lime of gas works, probably an impure sulphuret of lime, or lime combined with sulphuretted hydrogen, a gas, the most deleterious of all others to animal life, has been found by Earl Talbot to check the ravages of the wire worm. (*Proceedings of the Royal Agr. Soc.* in June 1841.)

## PART IV.

### STATISTICS OF BRITISH AGRICULTURE.

#### BOOK I.

##### PRESENT STATE OF AGRICULTURE IN THE BRITISH ISLES. (p. 1121.)

8493.—7711. *The evils of the botdy system of maintaining single farm servants*, are forcibly pointed out in the *Trans. High. Soc.*, vol. xiv. p. 122., and, as a remedy, the lodging the single men with the married ones recommended.

8494.—7711. *The employment of women in field labour* is very generally condemned by benevolent men, who allege that the association of numbers of persons, of both sexes, in the fields, demoralises them; and ample evidence is produced to prove that they are in many places demoralised. On the other hand, it is denied that there is anything in the nature of the congregation of both sexes in the fields morally worse than their congregation on the basement floor of a nobleman's house, in a large workshop or factory, in a drawing-room or ball-room, or in a public park or garden. "If in the drawing room or at the ball, or anywhere else, where the rich classes congregate, there is more decorum and refinement of manners; it is not because their inherent nature is different, or that the passions slumber; it is because they, the refined, have been taught, and made to feel the value of outward decorum. Whether in the servant's hall, or in the milliner's shop, or in the factory, or in the farm-field, we look for good behaviour, we shall find it; but we shall find it existing in a lesser or greater degree, according to circumstances other than the mere associating of a number of persons together. Are there not factories in England where the workers are educated and trained in moral decorum, and brought together in social parties occasionally, that they may exercise refinement of manners, and cultivate the higher sentiments of our moral nature? And are there not factories where the workers are neglected, and ignorant, and debased? Are there not workshops in the metropolis where the associated hands have the most scrupulous care paid to their physical and moral comforts, the results of which they show to all their conduct, in the shop and out of it? And is it not a notorious truth, that in the same metropolis the greater number of workshops, and those who are mistresses and masters and workers in them, are distinguished for conduct quite the reverse? And have we not an aristocracy with large establishments of domestic servants, some of which establishments might be a pattern to any school of moral instruction; while others in licentiousness are a disgrace to civilisation and the age we live in? Have we not an orderly, ay, a virtuous and well-mannered population of both sexes working in the farm-fields of Northumberland, Cumberland, Roxburghshire, Berwickshire, and the Lothians? And have we not, according to the evidence in the *Report of the Special Assistant Poor-law Commissioners on the Employment of Women and Children in Agriculture* (presented to Parliament in June, 1843), a population in Wilt and Dorset distinguished for their poverty and their vice? No, no; it is not because men and women, and girls and boys, associate in the fields promiscuously, that they are demoralised, that they become foul-tongued and ill-mannered. The association of the sexes in all conditions of life has a tendency to refine the manners, and restrain licentiousness, if no other cause to the contrary be at work. The farm-labourers are no exception.

1199 (\$8495.)

"We must go deeper for the causes of demoralisation than the mere assembling together of men and women in the fields. It is said by nearly all the witnesses that the women who work in the fields make neither good housewives nor good domestic servants. Now, to be neither a good housewife, nor a good household servant, is a grievous charge against outfield labour, were outfield labour chargeable with a result so much to be regretted. But the cause of the Dorset and Wilt, and Somerset and Devon women who have worked in the fields being such thriftless housewives, as they are mentioned to be in the *Reports* mentioned, is quite a different cause from that assigned. It is just as different as possibly can be, for it is that the unstable nature of all agricultural engagements in the south of England begets a precariousness of employment, with small and uncertain wages; which, by making good furniture and clothes, and family stores of provisions, unattainable, renders good housekeeping impossible."

The remedy which the admirable writer quoted suggests is, "Not the curtailment of the employment of women in the field, but an extension of it; a thorough revision of all the engagements between landlord and tenant; the complete emancipation of the tenantry from political subjection; the abolition of the variable rates of wages, dependent on a man's being married or unmarried, the establishment of agricultural schools for farmers; of national schools for all children, with no religious intermeddling whatever, save through the influence that may be exercised in the pulpit and in visitation to the houses of parents, an enactment compelling cottages to be equally good with those lately built by the Duke of Wellington for his labourers at Strathfieldsaye, with gardens not less in size, to wit, each a quarter of an acre; or as good as those cottages built for their workpeople by the Messrs. Ashworth and some other Lancashire manufacturers, as described in the *Sanitary Report of the Poor Law Commissioners*, published in 1842, and *Suppl. Encyc. Cott. Arch.* p. 1154. To discourage the giving of beer to labourers as a part of their wages. To encourage the paying of workpeople by so much a day, or week, or month, or year, and not by piece-work. To give tenant farmers full power to break up all old grass lands, and crop each his own farm, as he sees most fit; that is, if he proves himself to be trustworthy in regard of knowledge and capital. To give him security of tenure, that he may obtain capital: To take from him, at once and for ever, all delusion about protection from commercial competition, and let increased commerce give him an increased demand for his produce. To have all rents regulated by the prices of produce. To depart from the ruinous custom of an incoming tenant paying for all the work which the outgoing tenant has done in improvements, real or supposed. To let each tenant, on the contrary, come in free, and commence with his capital to improve his farm himself, giving him at least twenty years to reap the benefits, so that when he goes out he may carry the profits of his improvements with him, and not take their supposed value out of the pocket of his successor. To give better diet to the really helpless of the poor in the workhouses, and sufficient out-door relief to the aged who may desire to remain in the home of their affections. To send all able-bodied labourers who are willing to work and cannot find employment, to the cultivation of the crown lands, or other estates that may be procured and used for the purpose of agricultural schools; but never to send them to break stones or grind bones in a workhouse, as a punishment. To put an end to all poaching and poachers, by putting an end to all game-laws, and giving gamekeepers a more useful employment.

These are a few of the remedies for the present condition of the farm labourers. They are hastily

1901

thrown together. Some of them are, of necessity, remote; others I believe to be near at hand; all of them, I believe, must be adopted and carried out before the deplorable state of agricultural England alters from what it is. (*One who has whistled at the Plough in Morn. Chron.*, June 24th, 1843.)

8495.—7784. 11. *The application of steam to machinery for raising the water from fen and low lands.* We have mentioned (§ 7785), that steam had been employed for this purpose in Cambridgeshire; and we have since learned from the account of a trial in the newspapers (see *Times* for July, 1834), that a gas engine has also been so employed in the Cambridge fens. We are now enabled, through the kindness of Mr. C. H. Capper, engine-maker, Union Foundry, Birmingham, to figure and describe a steam-engine and lifting machine of a very superior description, which that gentleman has erected on the estate of — Drake, Esq., at Stainfield in Lincolnshire. "The great advantage," Mr. Capper observes, "of bringing fen and low lands (formerly rendered useless by floods) into cultivation, by a small outlay of capital, must be my apology for troubling you with so minute a description of the draining machine I have erected for that purpose; and, as the same may be of use to a few, I shall feel obliged if you will give it a place in your work, and at the same time add, that by the great improvements which the use of locomotive carriages has made in high-pressure engines, I am enabled to say that as effective an engine as the one described might now be completed for a much less amount, or, if the landowners whose lands are subject to floods were to subscribe, a movable draining-machine might be made, at a very small expense."

Fig. 1199. shows the elevation of a six-horse portable condensing steam-engine, working a second shaft, marked *c*, in *figs* 1200, 1201, and 1202. On this shaft, the large water-wheel *d* is fixed. This wheel revolves in a brick or stone casing, similar to that formed for the wheel of a common water mill, but so accurately fitted as not to allow of any water passing by either of the sides of the paddles, or by the front; because this wheel acts by its paddles lifting the water from the bottom of the wheel-race up against the breastwork, and then throwing it over the sluice *e*. This sluice is formed of movable boards, to admit of regulating the lift of water at pleasure, from 3 feet to 8 feet in height. The water, being raised and thrown over the sluice *e*, falls into the pond or receiver *f*, whence it is carried off at as high a level as it will run; in this case, at about 3 feet higher than the surface of the lands to be drained, and about 6 feet higher than the bottom of the drains. At the lower end of the trough there is a sluice, *g*, for regulating the quantity of water introduced into the lifting wheel, because, if this were too great, the power of the steam engine might be insufficient to turn the wheel, or the machinery might be injured. The wheel, as it will be seen, consists of eight iron paddles, fixed to an octagon iron casing; each paddle acts by lifting up a portion of water from the boom of the wheel-race, and raising it to the top of the

1802

sluice *g*. When the whole of the water, or nearly so, is lifted up, of course the boards composing the sluice *g* must be attended to, lest the water force its way back again upon the wheel.

Fig. 1200. is a ground plan of the boiler, engine, and water-wheel; in which *a* is the boiler; *b*, the engine; *c*, the water-wheel shaft; *d*, the paddles of the water-wheel; *e*, the upper sluice, over which the water is thrown; *f*, the pond or reservoir which receives the water; and *g*, the lower sluice, placed across the drain which conveys the water to the wheel-race.

Fig. 1201. is a section through the steam-engine and the water-wheel; in which *a* is the boiler; *b*, the engine; *c*, the shaft or axle of the water-wheel; *d*, the paddles; *e*, the tube for supplying water to the boiler; *f*, the steam pipe; *g*, the fly-wheel; *h*, the spur-wheels; and *i*, the roof.

Fig. 1202. is a longitudinal section through the water-wheel, the trough, and the two sluices; in which *c* is the axle of the water-wheel; *d*, the paddles; *e*, the upper sluice, over which the water is thrown; *f*, the pond or reservoir to receive the water before it is carried off to the nearest river; *g*, the trough or wheel-race; and *h*, the sluice to regulate the admission of the water from the land to be drained.

Fig. 1203. is a section through the boiler lengthwise; in which *a* is the boiler; *b*, the fire-place, and flue round the boiler; *c*, the ash-pit; *d*, the safety valve; *e*, the tube for supplying water to the boiler; *f*, manhole for cleaning out the boiler; and *g*, the chimney.

8496. *Action of the machine.* After these particulars, little description will be needed; for it must be evident that, when the engine is set in motion, it will, by means of the wheel and pinion *r*, turn the water wheel *d* of about its centre *e*; and that, when set in motion, each of the arms will lift a quantity of water from the trough, or wheel-race, *m*, over the sluice *s* (see fig. 1202.), at a higher level to the pond or reservoir, *f*, whence it may be taken away as circumstances may require.

8497. *The expense of the portable steam-engine, exclusive of carriage, and putting up, was about 280*l.*; that of the lifting wheel, exclusive of the masonry, about 70*l.*; and the total expense of the whole about 450*l.**

8498.—7943. *The study of chemistry by practical farmers* is strongly recommended by most writers on scientific agriculture; but this Dr. Madden considers an error. "I have noticed," he says, "with regret, that almost all the popular works hitherto written upon agricultural science have fallen into the one common error of endeavouring to make a chemist of the practical farmer; the authors all seem to think it necessary that, in order to the improvement of agriculture, every farmer must study chemistry. In this respect, however, I hold a totally different opinion. It appears to me that it would be a precisely analogous case, if writers on climate had said, that, in order to preserve health, it were absolutely necessary that every individual should study medicine. It is not an extended knowledge of chemistry that is required,—it is only a confidence in the results obtained by chemists that is absolutely necessary. If the farmer becomes acquainted with the facts as they apply to his practice, and if he has such confidence in these facts that he is willing to act in accordance to them, there is not the least necessity that he should occupy his time and burden his mind with all the abstruse processes of reasoning and experimental proof by which the chemist has been enabled to trace out their connection with the complex phenomena which they serve to illustrate." (*Trans. H. S.*, vol. xiv. p. 616.)

8499. *Improvements.* Professor Johnston of Durham, one of our first agri-

1203

Scale

cultural chemists, says, "Farmers are proverbially slow in adopting improvements: it is well that they are so; for if they were to adopt every thing which is new, they would most likely suffer many disappointments." The same author observes, that "prudence and economy are the soul of agriculture; and the balance of accounts at the end of the year is the criterion of the system pursued." (*G. C.*, 1843, p. 118.)

8500. *Experience and experiments.* In Professor Henslow's lectures before the Royal Agricultural Society, the connection between agricultural science and practice is clearly pointed out. Experience is the only source of scientific knowledge, and this can only be obtained by a long series of observations

and experiments, carried on, not by one person, but by many. Subsequently the Professor drew up a scheme by which the same experiment may be repeated in any number of places all over the country. See his Letters to the Farmers of Suffolk (*Gard. Mag.* 1843, p. 518.), Professor Henslow's scheme for co-operation, and Professor Johnston's suggestions. (*G. C.* 1843, p. 186.) "All England," Professor Henslow observes, "might be converted into one great experimental farm, if our different agricultural societies would prepare accounts of the exact mode in which some hundred farmers might perform a set of easy comparative experiments at the same time, and send in the results of them. This is what is most needed for accelerating the present jog-trot progress of agriculture into something like a railroad pace of advancing." (*G. C.* 1843, p. 186.) "Trust not implicitly to the suggestions of the most celebrated chemists, nor adopt their notions into your practice, without previously making a set of comparative experiments for yourselves, in order to test the value of their suggestions. Secure co-operation; act together by hundreds and thousands in attending to directions and in registering results. Such decided improvements in the art of culture will then be struck out for you, that your important interests will be able to maintain that state of prosperity which is so essential to the general well-being of the country." (*G. C.* 1843, p. 171.)

1801. *Model farmer*, which for many years have been adopted in France, Germany, and even Russia, have lately begun to be formed in Britain. One is commenced on the estate of Lord Ducie in the vale of Gloucester; one is in progress in Yorkshire, for the Yorkshire Agricultural Society, besides some in Ireland. (*Gard. Mag.* 1840, p. 564.)

1802. *The English Agricultural Society*. The idea of this society was first suggested by Lord Spencer, at the dinner after the show of the Smithfield club in the beginning of 1836, and a meeting was held for that purpose, on the 9th of May following. (*Q. J. A.*, vol. ix. p. 116.)

1803. *The Royal Agricultural Improvement Society of Ireland* was established in February, 1831. An account of its progress will be found in the *Brit. Farm. Mag.*, n. s., vol. vii. p. 74.

1804. *Schools for the instruction of farmers' sons in the physical sciences* were recommended in 1834 by Mr. William Hawkins, of Hitchin, Hertfordshire. (*Q. J. A.*, vol. v. p. 39.)

1805. *A Farmers' lending Library*, proposed to be established in Liverpool. (*B. F. M.*, n. s., vol. iv. p. 264.)

1806. *Cottagers' Garden Societies*, strongly recommended by Mr. Manteath, of Closeburn. (*Q. J. A.*, vol. iv. p. 791.)

1807. *The great obstacles to agricultural improvement at present*, are want of sufficient capital employed in cultivation; the absence of due security to any capital employed in cultivation; the absence of due security to any capital that might be applied; and the otherwise insecure and illiberal foundation on which agricultural polity rests; and the general aversion of landowners and wealthy individuals to make any outlay that would diminish their yearly revenue; and from their considering capital to consist only in ready money that is available; and from their being unable to connect it with improvements that would increase the yearly profit. A moneyed man buys a portion of land, and expects a certain yearly return from it in an uncultivated state; whereas if any part of the capital were expended in improving a smaller quantity of surface, a much greater annual revenue would be derived; for, in many instances, the first crop of improvement has paid rent and all expenses, and left the future return for profit and increase of the annuity. (*Donaldson's Treatise on Manures*, &c. p. 341.)

#### CHAP. IV. — Bibliography of British Agriculture, from 1832 to August 1843. (p 1206.)

1829—32. *Anon.*

*Transactions of the Agricultural and Horticultural Society of India*. Vols. I. and II. Serampore and Calcutta. (*G. M.* 1834, p. 440.; 1836, p. 519.)

1829. *Dawson, Mr. Robert*, late agent to the Australian Agricultural Company, New South Wales.

*Statement of his Services, &c.*, with a Narrative of the Transactions he received, &c. Lond. Pamph. 8vo. (*G. M.* 1830, p. 86.)

1830. *Denson, John, sen.*, market gardener near Cambridge.

*A Farmer's Voice to Landowners*, on the best Means of benefiting Agricultural Labourers, and of reducing Poor-rates. Cambridge. Pamph. 8vo. (*G. M.* 1831, p. 80.)

1830. The Committee for ameliorating the Condition of the Poor at Saffron Walden.

*Report, &c.* Saffron Walden. Pamph. 8vo. (*G. M.* 1831, p. 315.)

1830. *The Doncaster Agricultural Association*. Report of the Committee on Marginal Wares as a Fallow Crop. Pamph. 8vo. (*G. M.* 1830, p. 562.) Report on the Turnip-cult. Lond. Pamph. 8vo. (*G. M.* 1830, p. 100.)

1831. *Anon.*

*An Address to the Labouring Classes, on their Duties, &c.* E. in. Pamph. 8vo. (*G. M.* 1831, p. 302.)

1831. *Anon.*

*Facts and Illustrations demonstrating the important Benefits derived by Labourers from possessing small Portions of Land*. Monthly Numbers. Lond. 8vo. (*G. M.* 1831, p. 302.)

1831. *Barber, —*, a bookseller at Lewes in Sussex.

*Library of Agricultural and Horticultural Knowledge, &c.* Lewes. 8vo. (*G. M.* 1831, p. 315.)

1831. *Clapham, James, Esq.*, an accountant in Edinburgh, late editor of the *Farmer's Magazine*.

*System of Agriculture from the Encyclopædia Britannica*. Edin. 4to. (*G. M.* 1832, p. 120.)

1831. *Lawce, E. J.*, land and mineral surveyor, Lewisham.

*The Golden Farmer*, being an attempt to unite the Facts pointed out by Nature, in the Sciences of Geology, Chemistry, and Botany, with practical Operations of Husbandry, to enable them to grow more Corn, and increase the Employment of the Labourer. Lond. (*Brit. Farm. Mag.* vol. vi. p. 53.)

1831. *Lawrence, Charles, Esq.*, of Cirencester.

*Practical Directions on the Cultivation and general Management of Cottage Gardens; with Plans for laying them out for Five Years*; also, Hints on keeping Pigs, on Services, &c. Pamph. 8vo. 6d. Cirencester. (*G. M.* 1831, p. 216.) A new edition in 1843. (*G. M.* 1845, p. 342, and p. 397.) The best of all the gardening books or pamphlets for the common labourer.

1831. *Sussex Association for improving the Condition of the Labouring Classes*

*Quarterly Report*. Lond. Pamph. 8vo. (*G. M.* 1832, p. 300.)

1832. *Horion, Richard*, land steward and surveyor.

*Tables for planting and valuing Underwood and Woodland; also Lineal, Superficial, Cubical, Wagon, Marketing, and Decimal Tables; together with Tables for converting Land Measure from one Denomination into another, and Instructions for measuring Round Timber*. Small 8vo. Saffron Walden. (*G. M.* 1832, p. 308.)

1832. *Nile, W. B.*

*Remarks on the Importation, and Results of the Introduction of the Cachemire and Angora Goats into France; and the extraordinary Properties of the new Race, Cachemire-Angora; with its Capability of also rendering the common Goat of Value to the Colonists of New South Wales and Van Diemen's Land*. Lond. Pamph. 8vo. (*G. M.* 1832, p. 452.)

1832. *Huffin, Edmund*.

*An Essay on Calcareous Manures*. Petersburg, Lower Virginia. 8vo. (*G. M.* 1830, p. 156.)

1832. *Drummond, W., and Sons*, nursery and woodmen, Stirling.

*Report of their Exhibition of Agricultural Productions, with Communications on Wedges and The Draining; Thorough Draining, and Deep Ploughing; Bones as a Manure; and the Improvement of Agricultural Plants, &c.* Stirling. Pamph. 8vo. (*G. M.* 1832, p. 530, and 1835, p. 447.)

1833. *Parnell, Sir Henry, Bart.*

*A Treatise on Roads, &c.* Lond. 8vo. (*G. M.* 1834, p. 519.) A second edition in 1838.

1833. *Purvis, M. A.*

*De l'Agriculture des Géralais, de la Bohême, et du Berry; et des Moyens de l'améliorer*. Paris. 8vo. (*G. M.* 1834, p. 134.)

1833-4. *Dielsch and Turnbull*, nursery seedsmen, Perth.

Report of the Exhibition of Agricultural Productions, Implements, &c., held on their Frontiers, with original Essays, &c. Pamph. 8vo. Fench. (G.M. 1834, p. 504.)

1833-A. *The Imperial and Royal Agricultural Society of Vienna.*

Verhandlungen der k. k. Landwirtschafts Gesellschaft in Wien. Vienna. 8vo. Continued. (G.M. 1835, p. 308, 1840, p. 308.)

1834. *Amos.*

Appeal to our Rules and Rules in Behalf of a Consolidation of the Post Office Roads, and Mechanical Conveyances for the Service of the State. Lond. Pamph. 8vo.

1834. *Amos.*

New Statistical Account of Scotland. Edin. No. 1. 8vo. 1834. *Blacker, William, Esq.,* Armagh, land agent to the Earl of Gosford and Col. Close.

Prize Essay on the Management of Landed Property in Ireland. Dublin. Pamph. 8vo.

An Essay on the Improvement to be made in the Cultivation of small Farms, by the Introduction of Green Crops, and House Raising the Stock thereon. Dublin. Pamph. 8vo.

The Claims of the Landed Interest to Legislative Protection considered. Armagh. Pamph. 8vo. 1835.

1834. *Kemp, Henry.*

An Address to the Landed Interest on the Decomposition of Soil for the Purposes of Manure. Lond. Pamph. 8vo. The discovery is not stated, the author informing us that he expects the *quid pro quo*, from the landed interest, or parliament. Lond. Pamph. 8vo. (G.M. 1834, p. 335.)

1834. *Lawson, Peter and Son,* seedsmen, Edinburgh.

Report on their Agricultural Museum. Edin. Pamph. 8vo.

1834. *Low, David, Esq.,* F.R.S.E., professor of agriculture in the university of Edinburgh.

Elements of Practical Agriculture, comprehending the Cultivation of Plants, the Husbandry of the Domestic Animals, and the Economy of the Farm. Edin. 8vo. (G.M. 1834, p. 447.)

A second edition appeared in 1836.

1834. *Percival, Williams, M.R.C.S.,* veterinary surgeon in the 1st Life Guards.

Hippatology; or, a Systematic Treatise on the Disorders and Lamenesses of the Horse, &c. vol. I. pp. 331. Lond. 8vo.

1834. *Rein, F. W.,* member of the Agricultural Society of the Cape of Good Hope, &c.

Observations on the Merino Sheep with reference to the Cape of Good Hope, &c. Cape Town. Pamph. 8vo. (G.M. 1835, p. 534.)

1834. *Stephens, George,* land drainer, Edinburgh. The Practical Irrigator and Drainer. Edin. 8vo. (G.M. 1834, p. 233.)

1834. *Sutton, John,* of Fisherton Anger, near Salisbury, Wilts.

An Important Discovery for the Destruction of the Turnip Fly, &c. Salisbury. Pamph. 12mo. (G.M. 1834, p. 154.)

1834. *Tessier, M.*

Annales de l'Agriculture Française, &c. Paris. Published periodically. (G.M. 1834, p. 449.)

1835. *Amos.*

Le Cultivateur, Journal Belge d'Economie Rurale, &c. Brussels. 8vo. (G.M. 1836, p. 261.)

1835. *Schirreff, Patrick,* farmer, Mungoswells, East Lothian.

A Tour through North America, made with reference to Agricultural Emigration. Edin. 8vo. (G.M. 1835, p. 197.)

1836. *Amos.*

A Comparative View of the Farm and Character of the English Race and Saddle Horse, during the last and present Centuries. Eighteen Plates. Lond. 8vo.

1836. *Hilgard, C., Esq.,* president of the Northamptonshire Farming and Grazing Society.

A Summary of Practical Farming; with Observations on the Breeding and Feeding of Sheep and Cattle; on Rents and Tithes; and on the Present State of Agriculture. Lond. (Brit. Farm. Mag., vol. x. p. 53.)

1836. *Lawson, Peter, and Son,* seedsmen and nurserymen to the Highland and Agricultural Society of Scotland.

The Agriculturist's Manual; being a Description of the Agricultural Plants cultivated in Europe, &c. Edin. 8vo.

Supplement to the Agriculturist's Manual. Edin. Pamph. 8vo. 1842. (G.M. 1836, p. 436.)

1836. *Le Couteur, John, Esq.,* colonel, &c. On the Varieties, Properties, and Classification of Wheat. Jersey. Pamph. 8vo. (G.M. 1837, p. 607.)

1836. *Lefevre, Charles Shaw, Esq., M.P.,* chairman of the select committee appointed to inquire into the state of agriculture.

Remarks on the present State of Agriculture, in a Letter addressed to his Constituents. Lond. Pamph. 8vo.

1836. *Lewis, George,* tenant in Boghillie, near Kirkcaldy.

Observations on the present State and future Prospects of Agriculture, illustrative of the Advantages of an Experimental Farm. Cupar and Edin. Pamph. 8vo.

1837. *A Dunbartonshire farmer.*

The Failure of the Potato Crop ascertained and demonstrated from Analogy; with a Remedy and Test for the present Seed to prevent Failure. Glasgow. Pamph. 8vo.

1837. *Aitken, William, Castle-Douglas.*

The Potato rescued from Disease and restored to pristine Vigour, by a Plan of Kelping and Cultivation founded on the natural Principles of the Vegetable Economy. Edin. Pamph. 8vo.

1837. *Amos.*

The Gardener's Gazette, and Weekly Journal of Science, Literature, and General News, more especially the Sciences of

Horticulture, Botany, Natural History, and Agriculture. Lond. 8vo. continued weekly, price 6d.

1837. *D'Aubenton, M.,* garde générale des Forêts, &c.

Château des Ombres, &c. Lyons. Pamph. 8vo. (G.M. 1836, p. 181.)

1837. *Louey, N. V. A.*

De l'Economie des Ecuries, ou de la Méthode de Pierre Jaussin, &c. Paris. Pamph. 8vo. (G.M. 1838, p. 184.)

1837. *Siegt, William,* nursery and seedman, Lincolnshire.

Practical Remarks on the Failure of the Potato Crop, &c. Gainsborough. Pamph. 8vo. (G.M. 1837, p. 519.)

1837. *Townsend, the Rev. William H.,* rector of Aghada, Cloyne.

Directions on Practical Agriculture for the Working Farmers of Ireland, &c. Cork. Pamph. 8vo. (G.M. 1838, p. 340.)

1838. *An experienced farmer.*

A new Treatise on Agriculture and Grazing. Lond. Pamph. 8vo. (G.M. 1838, p. 294.)

1839. *Dickson, Walter B.,* a name assumed by James Rennie, a well-known author.

Poultry, their Breeding, Rearing, Diseases, &c. Lond. 8vo. (G.M. 1838, p. 296.)

1838. *Handley, Henry, Esq., M.P.*

A Letter to Earl Spencer on the Formation of a National Agricultural Institution. Lond. Pamph. 8vo. (G.M. 1838, p. 181.)

1838. *Hughes, Thomas, Esq.,* civil engineer.

The Practice of making and repairing Roads; of constructing Footpaths, Fences, and Drains; also, a Method of comparing Roads, with reference to the Power of Draught required; with Practical Observations, intended to simplify the Mode of estimating Earthwork in Cuttings and Embankments. Lond. 8vo. (G.M. 1842, p. 471.)

1838. *Lance, E. J.,* author of the *Golden Farmer*, &c.

The Hop Farmer; or, a complete Account of Hop Culture, &c. Lond. 8vo. (G.M. 1838, p. 296.)

1838. *Menclith, James Stuart, Esq.*

Farmers versus Rooks. Ayr. Pamph. 8vo.

1838. *Morton, John, Esq.,* land steward to Lord Ducle.

On the Nature and Property of Soils; their Connection with the Geological Formation on which they rest; the best Means of permanently increasing their Productiveness; and on the Rent and Profits of Agriculture. Lond. Small 8vo. (G.M. 1838, p. 151.)

1838. *Stewart, J.,* veterinary surgeon, and professor of veterinary medicine in the Andersonian university, Glasgow.

Stable Economy; or, a Treatise on the Management of Horses, in relation to Stabling, Grooming, Breeding, and Working. Edin. 8vo.

Advice to Purchasers of Horses. Three Engravings. Edin. 8vo.

1838. *Tollard, aine, C.,* seedman and nurseryman.

Traité des Végétaux qui composent l'Agriculture, &c. Treatise on the Plants which are cultivated in Agriculture, Planting, and Gardening; containing the most striking Characters, the Points of Difference, and the Qualities and Uses of all Plants, more particularly those little known or deserving of Culture; followed by Considerations respecting Nurseries and Plantations, and a Monthly Journal of Work to be done in the Forest, the Garden, and the Farm. Paris. Small 8vo. (G.M. 1840, p. 663.)

1838. *Waterton, Charles, Esq.*

Essays on Natural History, with an Autobiography of the Author. Lond. 12mo.

1839. *Davy, Sir Humphry, Bart., LL.D.,* F.R.S., &c.

Elements of Agricultural Chemistry; in a Course of Lectures for the Board of Agriculture, delivered between 1802 and 1812. 6th edit. 8vo. Lond. (G.M. 1840, p. 95.)

1839. *Main, James, A.L.S.,* author of various works.

The Young Farmer's Manual: showing the Practice and Principles of Agriculture, as applicable to Turnip Land Farms in the South of England; with collateral Observations and Remarks on Agricultural Cattle, Plants, Implements, &c. Lond. 8vo. (G.M. 1839, p. 583.)

1839. *Royal Asiatic Society of Great Britain and Ireland.*

Proceedings of the Committee of Commerce and Agriculture. Lond. 8vo. (G.M. 1839, p. 177.)

1839. *Sinclair, George, F.L.S.H.S., &c.*

Horrua Grandensis Webernensis, &c., 4th edit. much reduced in price. Lond. 8vo. (G.M. 1839, p. 702.)

1839. *Spradley, John.*

A Treatise on Agriculture, adapted to the Soil and Climate of Ireland, comprehending the Nature, Properties, and Improvements of Soils; the Structure, Functions, and Cultivation of Plants; and the Husbandry of the domestic Animals of the Farm. Dublin. 8vo. (G.M. 1840, p. 54, and 1842, p. 378.)

1839. *The English Agricultural Society.*

Journal, &c. Lond. 8vo. Published in parts; of which 3 vols. and Part I. of Vol. IV. have appeared. (G.M. 1839, p. 345; 1840, p. 169; 1841, p. 79, and 625.)

1840. *A Lanermuir Farmer,* the late Mr. John Fairbairn of Hallyburton.

A Lanermuir Farmer's Treatise on Sheep in High Districts. 1840. *Amos.*

Twenty Years' Experience in Australia, &c. 3d edit. Lond. Small 8vo. (G.M. 1840, p. 299.)

1840. *A Proprietor (Sir F. A. Mackenzie, Bt.)*

Essay for the Use of Highland Tenants and Cottagers. In 2 vols. 8vo. (G.M. 1840, p. 214.)

1843. *Blacklock, surgeon, Dumfries.*  
A Treatise on Sheep. Dumfries. 8vo.
1843. *Donaldson, John, land steward.*  
Bayle's Art of valuing Herbs and Tillages, and the Tenant's Right in sowing and cutting Furrows, explained by several Specimens of Valuations, and Remarks on the Cultivation pursued on Soils in different Situations. Adapted to the Use of Landlords, Land Agents, Apprentices, Farmers, and Tillagers. 8th edn. Lond. 8vo. (G.M. 1840, p. 94.)
1843. *Jackson, James,* author of various prize essays of the Highland and Agricultural Society of Scotland.  
A Treatise on Agriculture and Dairy Husbandry. Edin. 8vo. (G.M. 1840, p. 659.)
1843. *Liebig, Justus, M.D. Ph. D. F.R.S., &c.*  
Organic Chemistry in its Application to Agriculture and Physiology. Edited from the manuscript of the author by Louis Richter, Ph.D. Lond. 8vo. (G.M. 1840, p. 604, and 1842, p. 128.)
1843. *Lowson, J. and M., and Westwood, J.O. Esq.*  
Kobler's Treatise on insects injurious to Gardeners, Foresters, and Farmers. Translated from the German. Lond. Small 8vo. (G.M. 1840, p. 92.)
1843. *Morton, John, Esq.*  
Report on the present State of Whitfield Farm, and the Plan proposed for improving it. To which is added, a Letter to the Trustees of Philip Pusey, Esq., M.P. for Berkshire. Lond. Pamph. 12mo. (G.M. 1840, p. 216.)
1843. *Anon.*  
The Cottage's Monthly Visitor. Lond. In small 8vo numbers monthly, forming one volume annually. 4s. 6d.
1843. *Anon.*  
The Hand-book of Agriculture; chiefly for the Use of those interested in the Allotment System. Lond. 12mo.
1843. *Barclay, Captain, of Urr.*  
An Agricultural Tour in the United States of Upper Canada with Miscellaneous Notices. Edin. 8vo.
1843. *Darbyney, Charles, M.D., F.R.S., M.R.S.A., &c.*  
Three Lectures on Agriculture; delivered at Oxford on July 22nd, and Nov. 25th, 1842, and on Jan. 20th, 1843; in which the Chemical Operation of Manures is particularly considered, and the Scientific Principles explained upon which their Efficacy appears to depend. Oxford. 8vo. (G.M. 1843, p. 270.)
1843. *Denton, J. Bailey,* land surveyor, London.  
Outline of a Method of Model Mapping, &c. Lond. Pamph. 8vo. (G.M. 1841, p. 626.)
1843. *Doyle, Martin,* a name assumed by an Irish clergyman.  
A Cyclopedia of Practical Husbandry. 8vo. Dublin.
1843. *Gilly, the Rev. Dr., Canon of Durham.*  
The Tenacity of the Reader. An Appeal in their Behalf. Pamph. 8vo. (G.M. 1842, p. 51.)
1843. *Lindley, John, Ph. D. F.R.S.,* professor of botany in the University College, &c. &c.  
The Gardener's Chronicle. A stamped newspaper of rural economy and general news. Lond. Folio, continued weekly, price 6d.
1843. *Meisner, J.,* curator of the gardens at the castle of Heidelberg, author of a description of that castle, &c.  
Die Geranien-arten und Wiesengraser in botanischer und oekonomischer Hinsicht, that is, the Gerani and Meadow Grasses botanically and economically considered. Fests. Heidelberg. (Gard. Chron. 1841, p. 755. and 767.)
1843. *Owen, Robert.*  
A Development of the Principles and Plan on which to establish Self-supporting Home Colonies, &c. Lond. 4to. (G.M. 1841, p. 625.)
1843. *Perce, the Hon. H. W.*  
An Account of the Settlements of the New Zealand Company, from Personal Observations during a Residence there. Lond. (Gard. Chron. 1841, p. 735.)
1843. *Robert, Owen Owen.*  
Hints on Agricultural Economy as the Antidote to Agricultural Distress. Pamph. 8vo. Lond. (Gard. Chron. 1841, p. 779.)
1843. *Tattersall, George,* surveyor.  
Specifying Architecture. Lond. 4to. (G.M. 1842, p. 22.)
1843. *Wallon, William.*  
A Memoir addressed to Proprietors of Mountain and other Waste Lands, and Agriculturists of the United Kingdom, on the Naturalization of the Alpaca. Pamph. 8vo. Lond. (Brit. F.W. n. s., vol. v, p. 263.)
1843. *White, W. H., M.B.S.,* secretary to the Meteorological Society.  
On the Theory of the Weather Prophets, and the Comparative Success of their Predictions. Pamph. 8vo. Lond. (G.M. 1841, p. 379.)
1843. *Anon.*  
Advice to Farmers how to double their Crops by new Fertilizers. Pamph. 8vo. Lond.
1843. *Anon.* A tourist from the north.  
Suggestions offered, and Data given, in proof that a sufficient Supply of Broad Corn for the Inhabitants of Great Britain, the Growth of their own Soil and Produce of their own Industry, may be obtained in the year 1845, and for an indefinite Period to come. Pamph. 8vo. Lond. (Brit. F.W. n. s., vol. v, p. 425.)
1843. *Anon.*  
The Vegetarian. Lond. (Brit. F.W. n. s., vol. vi, p. 151.)
1843. *Anon.,* with a preface by Henry Drummond, Esq.  
On the Condition of the Agricultural Classes of Great Britain and Ireland; with Extracts from the Parliamentary Reports and Evidence, from 1835 to 1840, and Remarks by the French Editor published at Vienna. 12 vol. Lond. (Brit. F.W. n. s., vol. vi, p. 151.)
1843. *Chavrus, F.,* a dealer in potatoes in London.  
Catalogue of Potatoes. Pamph. 8vo. Lond.
1843. *Conningham, James,* surveyor, Greenlaw.  
Seven Lithographic Designs for the Improvement of Farm Cottages and Stables. Edin. 8vo.
1843. *Denton, J. Bailey.*  
General Drainage and Distribution of Water, &c. Lond. Pamph. 8vo. (Brit. F.W. n. s., vol. vi, p. 267.)
1843. *Donaldson, John, land steward;* editor of the fifth edition of *Bayle on Herbs and Tillages*, and author of a number of agricultural essays.  
A Treatise on Manures, their Nature, Preparation, and Application, with a Description and Use of the most approved British Grasses; to which is added a Miscellaneous Article on Potatoes with an Estimate and Description of an Example Farm of Three Hundred Acres, illustrated with Cuts of Farm-buildings. Lond. 8vo. (G.M. 1842, p. 231.)
1843. *Grog, Robert Hyde.*  
Scottish Farming in the Lothians. A Letter addressed to the Editor of the Manchester Guardian. Lond. Pamph. 8vo. (G.M. 1842, p. 269.)
1843. *Hubbard, J. G. Esq.*  
Validation of a Fixed Day on Corn. Lond. (Brit. F.W. n. s., vol. vi, p. 151.)
1843. *Johnson, C. W. Esq., F.R.S., &c.*  
The Cottage Farmer's Assistant in the Cultivation of his Land, and Book of the Household. Lond. (Brit. F.W. n. s., vol. vi, p. 424.)
1843. *Johnson, C. W. Esq., F.R.S., &c.*  
Agricultural Chemistry for Young Farmers. Lond. (Brit. F.W. n. s., vol. vi, p. 158.)
1843. *Johnson, Gilbert W., F.R.S.*  
The Farmer's Encyclopedia, and Dictionary of Rural Affairs. Lond. 8vo. (G.M. 1841, p. 625.)
1843. *On increasing the Depth of Soils.* Lond. Pamph. 8vo. (G.M. 1843, p. 5.)
1843. *Johnston, James F.W., M.A., F.R.S.S. L. and E.*  
Elements of Agricultural Chemistry and Geology. Edin. Small 8vo. (G.M. 1842, p. 372.)
1843. *Lectures on Agricultural Chemistry and Geology.* Edin. 8vo.
1843. *Suggestions for Experiments in Practical Agriculture.* Edin. Pamph. 8vo. Nos. I. and II.
1843. *What can be done for English Agriculture?*  
A Letter to the Marquis of Northampton. Edin. Pamph. 8vo. (G.M. 1843, p. 636.)
1843. *Liebig, Justus, M.D. Ph. D., F.R.S., M.R.S.A.,* professor of chemistry in the university of Giessen.  
Annual Chemistry; or, Organic Chemistry, in its Application to Physiology and Pathology. Edited from the Author's Manuscript, by William Gregory, M.D., F.R.S.E., &c. Lond. 8vo. (G.M. 1843, p. 81.)
1843. *National Anti-Corn-Law League.*  
The Three Price Essays on Agriculture and the Corn Law. Manchester. Pamph. 8vo. (G.M. 1845, p. 80.)
1843. *Parnell, Richard, M.D., F.R.S.E.*  
The Grasses of a Land; containing a scientific Description of each Species, Remarks on their Use in Agriculture, &c. Edin. 8vo. (G.M. 1842, p. 642.)
1843. *Potter, W. H., M.R.A.S.,* agricultural chemist.  
A Word or Two on Guano, and a new Manure Artificial Guano. Lond. Pamph. 8vo. (G.C. 1842, p. 565.)
1843. *Sibby, Priderius John, Esq.,* of Twizell.  
A History of British Forest Trees, indigenous and introduced. Lond. 8vo.
1843. *Squarry, Charles,* chemist.  
A popular Treatise on Agricultural Chemistry; intended for the Use of the Practical Farmer. Lond. 8vo. (G.M. 1845, p. 33.)
- 1843-43. *Stephens, Henry,* editor of the *Quarterly Journal of Agriculture.*  
The Book of the Farm. Edin. 2 vols. 8vo. (G.M. 1842, pp. 125, 292, and 636.)
1843. *Strachan, James,* teacher, Donaldson's school, Stonehaven.  
A new Set of Tables, for computing the Weight of Cattle by Measurement; the Quantity of Hay in Bicks of different Farms; the Value of Land, &c.; the Measurement of Drains and Dumbhills. Edin. 12mo. cloth.
1843. *Trimmer, Joshua.*  
Practical Chemistry for Farmers and Landowners. Lond. 8vo. (G.C. 1842, p. 567.)
1843. *West J.,* land-agent, &c., North Collingham, Newark, Notts.  
Remarks on the Management, or rather the Mismanagement of Woods, Plantations, and Hedge-row Timber. Newark. 8vo. (G.M. 1842, p. 470.)
1843. *Anon.*  
An Account of the Manure Guano, and authentic Experiments made with it, &c. Liverpool. Pamph. 8vo.
1843. *Anon.*  
The Farmer's Calendar and Diary of Agriculture and Gardening, for the Year 1845. 12mo. Lond. (G.M. 1845, p. 81.)
1843. *Buller, Samuel, Esq.,* author of the *Hand-book for Australian Emigrants.*  
The Emigrant's Hand-book of Facts, concerning Canada, New Zealand, Australia, Cape of Good Hope, &c.; with the relative Advantages each of the Colonies offers for Emigration, and practical Advice to assisting Emigrants. Glasgow. 12mo. (G.M. 1846, p. 184.)
1843. "Country Cousins."  
Timely Hints, addressed to the Landlords and Tenantry of England, Scotland, and Ireland; showing, in a few Words, the only obvious, and the only Means by which they can severally continue to thrive and pay fair Rents from the Soil.

under the present system, and prospective possible, Depreciation in Value of British rural productive Industry, &c. Lond. Pamph. 8vo. (G.M. 1843, p. 515.)

1843. *Henslow, the Rev. J. S., M.A.,* Rector of Hitcham, and professor of botany in the university of Cambridge.

*Lectures to the Farmers of Suffolk.* Lond. Pamph. 8vo. (G.M. 1843, p. 515.)

1843. *Johnson, Cuthbert W., F.R.S., &c.*

*On Guano as a Fertiliser.* Lond. Pamph. 8vo.

*Johnson, Cuthbert W., F.R.S., &c., and Jabez Hore.*

*The Annual Register of Agricultural Implements, illustrated by numerous wood engravings, with a Catalogue of the chief of those exhibited at the Derby Meeting, 1843. With a History of the Royal Agricultural Society of England. To be continued annually.* Lond. Pamph. 12mo.

1843. *Johnson, Cuthbert, W., F.R.S., and W. Sano, Esq.*

*The Farmer's Almanack for 1843.* Lond. 12mo. To be continued annually. (G.M. 1841, p. 526.)

1843. *Lawson, Peter and Son,* seedsmen to the Highland and Agricultural Society of Scotland.

*Treatise on the cultivated Grasses and other Herbage and Forage Plants, with the Kinds and Quantities of Seeds for sowing down land to alternate Husbandry, permanent Pasture, Lawns, &c.* Edin. Pamph. 8vo. (G.M. 1843, p. 183.)

1843. *London, J. C., F.L.S., H.S., &c.*

*The Gardener's Magazine, and Register of Rural and Domestic Improvement.* Lond. 8vo. Commenced in 1823, and continued monthly, price 1s. 6d.

1843. *Murray, Sir J., M.D.*

*Trials and Effects of Chemical Fertilisers, with various Experiments in Agriculture, &c.* Dublin. Pamph. Part I. 8vo.

1843. *Smith, Joseph A.*

*Productive Farming, or, a Familiar Digest of the recent Discoveries of Liebig, Davy, &c.* Edin. Pamph. Small 8vo.

1843. *Solly, Edward, Jun., F.R.S., L.S., &c.* experimental chemist to the Horticultural Society of London, lecturer on chemistry at the Royal Institution of Great Britain, &c.

*Rural Chemistry: an Elementary Introduction to the Study of the Science in its Relation to Agriculture.* Lond. Small 8vo. (G.M. 1843, p. 202.)

1843. *Tilley, T. G., Ph. D.*

*Agricultural Chemistry rendered simple for Practical Purposes.* Lond. 8vo. (G.C. 1845, p. 238.)

1843. *Trimmer, J., F.G.S.*

*Science with Practice, or, Guano the Farmer's Friend.* Lond. Pamph. 8vo.

1843. *West, J., land agent, &c.*

*An Agricultural Tract for the Times.* Pamph. 8vo. Col. lingham, Nova. (G.C. 1845, p. 265.)
